Although much could be said relative to this subject, it is not our purpose, nor does it come within the scope of this journal, to discuss it. From a medical point of view, it contains very little to interest the profession, except, perhaps, as a book of reference, and even in this respect it falls so far below the standard works on this subject as to make it comparatively valueless. The opening pages mention briefly the dates when such diseases as are considered epidemic were first recognized as distinct affections. Neither history nor description of these diseases is attempted, and, when throughout the book reference is made to them, it is merely to introduce the subject of numismatics. The book is well printed, and the plates, illustrating a great number of medals, are excellent.

A Handbook of Treatment (Notes on Hospital Practice). Edited and published by S. M. Miller, M. D. Philadelphia. Pp. 470, 8vo. [Price, cloth, \$4; sheep, \$4.50; half Russia, \$5.]

As a *vide-mecum* to the busy practitioner or the student of medicine, this little work, containing suggestions and hints such as the ordinary emergencies of an every-day practice may at any time call for, will be found of much value. It embodies the opinions and experiences of many of our most prominent practitioners in hospital and private practice.

BOOKS AND PAMPHLETS RECEIVED

Farmacopoea Nazionale e Generale, Materia Medica, e Terapia del Prof. Dr. C. Ruata, già Assistente di Materia Medica presso la R. Università di Padova. Contiene oltre ai preparati proprii, tutti i preparati farmaceutici delle Farmacopoe degli Stati Sardi, dell' Orosi, del Campana; della Farmacopoe Austriaca, Belga, Danese, Francese, Germanica, Inglese, Russa, e degli Stati Uniti d'America; l'azione dei farmaci e le indicazioni terapeutiche; i pesi e misure dei differenti Stati; suggerimenti pratici sul modo di ricettare. Verona e Padova: Drucker & Tedeschi, 1883. Pp. vii-970.

Sopra un Caso di Laparotomia per Occlusione Intestinale. Pel Dott. C. Ruata. Pp. 13. [Reprint from the "Gazzetta Medica Italiana—Provincia Venete."]

Transactions of the Thirty-second Annual Meeting of the Illinois State Medical Society, held at Quincy, May 16, 17, 18, 1882. Pp. 274.

Is Gonorrhoea a Bacteria Disease? By Newberry A. S. Keyser. Pp. 8. [Reprint from the "Maryland Medical Journal."]

The Connection of the Lower Organisms with Infectious Diseases. By W. T. Councilman, M. D., Baltimore. Pp. 12. [Reprint from the "Archives of Medicine."]

Tuberculosis as an Infectious Disease. By W. T. Councilman, M. D. Pp. 6. [Reprint from the "Maryland Medical Journal."]

A Study of the Malformations, Variations, and Anomalies of the Circulatory Apparatus in Man, etc. By Randolph Winslow, M. D., Baltimore. Pp. 40. [Reprint from the "Annals of Anatomy and Surgery."]

On the Treatment of Gunshot Wounds of the Abdomen in Relation to Modern Peritoneal Surgery. By J. Marion Sims, M. D., LL. D., etc. Pp. 32. [Reprint from the "British Medical Journal."]

Addresses delivered on the Occasion of the Dedication of Cooper Medical College Building. By Levi C. Lane, M. D., etc., and by Edward R. Taylor. Pp. 42.

NEW YORK, SATURDAY, MARCH 17, 1883.

VACCINATION IN THE FRENCH ARMY.

The French Minister of War has recently issued substantially the following instructions regarding the vaccination and revaccination of the army. Regimental medical officers, and those serving with detached bodies of troops, are henceforth charged with the service of vaccination. They are required to vaccinate or revaccinate all recruits at once on their joining the force, and to repeat the operation on individuals of previous contingents in whom it failed of success at first, repeating the attempt on all refractory subjects as often as possible during the four months following the first trial.

The operation is to be done with a needle or with a lancet, three punctures being made on each arm. At each puncture, or at most after every second puncture, the instrument shall be charged anew with lymph. Medical officers must establish and maintain an abundant supply of vaccine, giving preference to different sorts of vaccinifers in the following order: (1) infants not less than four months old, and of good health; (2) healthy adults not previously vaccinated; (3) healthy adults that have been vaccinated before; (4) animals. The effects of the inoculations and the evolution of the pustules shall be observed attentively, with a view to distinguishing with certainty between true and false vaccinia. The results are to be recorded only as successful and unsuccessful, doubtful cases being included under the latter term. No case shall be registered as successful unless the lesion presents the positive characteristics of the vaccine pock.

Every case of death from small-pox shall be made the subject of a report addressed to the director of the sanitary service of the *corps d'armée*, stating as precisely as possible: whether the disease was contracted in the barracks, in the hospital, in the garrison, or elsewhere; whether the person had been vaccinated, once or more than once, before or after his joining the army; whether the vaccination was successful or unsuccessful; what sort of vaccine it was done with; specifying, in short, all the circumstances tending to throw light upon the question of vaccination and revaccination.

In the main, no doubt these regulations will secure not only the efficient performance of vaccination in the French army, but also such a systematic and precise registry of the results of the operation that in years to come the statistics may be accepted as far more trustworthy and to the point than is commonly the case as regards the matter of vaccination on a large scale, whether in civil or in military life. There are some particulars, however, in which, we think, much will depend on the judgment of the individual medical officer, and others in which no

personal qualities of his whatever can overcome what we can not but consider as defects in the regulations.

In the first place, we question the wisdom of restricting any man who is fit to be an army surgeon to the use of any particular instrument for vaccination, and especially to the method by puncture. Then, too, several questions arise apropos of the injunction to renew the lymph on the instrument after, at most, every second puncture. How is it to be renewed? Is it to be plunged again and again into the actual pock on the vacciner's arm? Most probably, as the regulations seem to contemplate arm-to-arm vaccination as a rule. If such is the case, it is to be hoped that surgeons will improve on their instructions by seeing to it that no needle or lancet smeared with the blood of the person or persons to be vaccinated is brought into contact with the vacciner's open pock, but that a fresh instrument is used at each resort to the pock, or at least that the instrument is thoroughly cleansed. If such precautions are not taken, risk will be run of inoculating the vacciner with syphilis. But, is the needle or lancet to be charged with stored lymph? If it is, then the method by puncture is pretty sure, in our opinion, not to give the full benefit of the possibilities of vaccination, and many unnecessary failures will have to be recorded. Indeed, vaccination by puncture is open to a number of objections, which, however, it is not our present purpose to mention.

We think it would be far safer to let the regimental surgeon perform the operation of vaccination in his own way, cautioning him, perhaps, as to certain methods to be avoided, than to fix on him the responsibility of establishing and maintaining an abundant source of vaccine supply. Such an undertaking as that often taxes the ability of those who have been specially trained to it. We take it that "animals" (meaning calves, we presume) are named last in the list of vaccinifers to which preference is to be given, simply because their use is expensive. Surely, the French authorities can not mean to be understood as saying in general terms that a revaccinated man is to be preferred for this purpose to a calf. It is very much to be regretted, indeed, that adults, and especially those that have been vaccinated before, should be allowed to serve as vaccinifers under any ordinary circumstances. The resort to such questionable sources of vaccine may be allowable in the case of a body of troops so situated that nothing better is available, but most assuredly it should not be tolerated as a general thing.

As to the record of results, we are not told whether every one of the six inoculations in each case must give rise to a characteristic pock, in order to justify the registration of the case as successful, or whether a less number will suffice. We doubt if it is conducive to truthfulness of the record, too, to set down all doubtful results as failures, for we think it perfectly practicable to distinguish between lesions that are manifestly vaccinal, although not perfectly developed, and those that are traumatic or the result of complicating factors, and *a fortiori* between those of the former category and the entire absence of any result. We must express our hearty approval, however, of the injunction to repeat the operation again and again in cases of failure, and we have no doubt that its faithful observance

will astonish those who are under the impression that in the majority of cases revaccination necessarily fails of its object.

THE DISCUSSION OF ETHICS.

It is evident that the question of ethics is not generally regarded as having been finally disposed of, even in this State. The recent action of the Medical Society of the State of New York simply maintained the stand taken the year before, with the implied understanding that Dr. Koosa's resolution, generally interpreted to mean *no code*, but happily named by Dr. Elsberg, in a letter published in our last issue, the "*gentleman's code*," was to come up again for final action next year.

There has been but little public advocacy of the new code since it was re-affirmed last month, and for reasons, it seems to us, that are creditable to the good taste of its supporters. So far as the effect of any such advocacy in this State is concerned, it would have been nil, for the new code is a *fait accompli*; the only other reason that we have been able to see for defending it further is, a purpose to foster a sentiment in other States favorable to the adoption of an equivalent course of action—arguing a spirit of propagandism from which we trust that the people of New York, physicians as well as others, may ever remain as free as in the past.

While these considerations are perfectly obvious, and have rendered it improper for the medical journals of New York to speak editorially in favor of the new code, or for the champions of the latter to take the initiative on the subject in any way, since they had voluntarily thrown off all allegiance to the American Medical Association, and could not with any propriety seek to influence its action even indirectly—on the other hand, those who opposed the late action of the State society have been under no such restriction. That action of the society practically arraigns the code of ethics of the American Medical Association, and now is the proper time for its adherents to come to its support publicly. Such being the case, it is gratifying to find that Dr. Squibb is not the only man capable of defending the old code in a catholic and decorous way, and we are sure that our readers, whatever their individual impressions may be of the merits of the case, will profit by studying Dr. Flint's series of papers, the first of which is published in this number of the journal. The fact that Dr. Flint has passed much of his professional life in other parts of the country than New York, no less than his well-known probity, his entire freedom from anything approaching partisanship, his kindly way of viewing the acts and motives of his fellow-men, and his well-earned eminence as a practitioner and teacher of medicine, makes it peculiarly fitting that he should undertake the task in question.

But, the ball having thus been set in motion, it becomes perfectly proper for the supporters of the New York code, and those who prefer still another course of action, to resume the argument from which the considerations we have herein pointed out have hitherto restrained them. On that account, we are glad that Dr. Hopkins has decided to publish the paper he read

at the recent meeting of the State society, which also we have the privilege of inserting in this number of the journal. We trust that the discussion, since it must come, will engage the voices of other members of the profession of like qualifications, and not again degenerate into the abusive and unseemly squabbling that figured so largely in it prior to the late meeting of the State society.

THE MITCHELL ENTERTAINMENT FUND

This is not the first time we have asked our readers' attention to the relationship between the successful working of organized bodies of physicians and proper attention to the cheering and warming influence of that mild form of conviviality for the lack of which many a society of lofty aims has fallen far short of their fulfillment, even if it has not come to an untimely end. We all feel an instinctive confidence in any deserving enterprise that is set on foot by a party of men gathered together around the mahogany, and scarcely to a lesser degree is our trust strengthened by that dilute form of indulgence in good cheer that is commonly carried out in the standing posture, especially when it involves such an aggregation of individuals as to entail more or less jostling and the consequent zest of danger to clothing if not to person. Such a touch of nature might perhaps have soothed the disgusted philosopher of the Stanislaus after the "chunk of old red sandstone took him in the abdomen." Certain it is, that its effect on a congregation of medical men is in the highest degree conducive to permanence of the organization. We call to mind one of the most vigorous of our New York medical societies, that spent its early years in the chilling atmosphere of a lecture-room, with a blank dreariness diversified only by an occasional squabble over the constitution and by-laws. These conflicts proved mere goads, however, without the slightest roborant action, and the society seemed moribund. Its rejuvenation dates from the change involved in the introduction of a social element. So obvious is this fact to its members, indeed, that they are wont to confess to each other that it is the *ingesta* that hold them together.

If this is the case with a small special society, such as the one to which we have alluded, it is not on account of its being small, or because it is circumscribed in its scope, for the larger societies find themselves fain to call in the aid of the same subtle force from time to time. A striking example is to be found in the incident that occasions these remarks: namely, the gift of the sum of five thousand dollars to the College of Physicians of Philadelphia, by Dr. S. Weir Mitchell, the income to be used in defraying the expense of an annual entertainment. This sum, we understand, has been formally accepted by the college, and is to be known as "The S. Weir Mitchell Entertainment Fund." Here in New York, too, our larger societies find it necessary to pay tribute to human nature in the same way, but, so far as we know, no special provision is made for the requisite outlay of money. Individuals are always found among us who are quite willing to loosen their purse-strings, and we are inclined to think that too often the demand is met quietly year after year by very much the same fact. Being used by society, they have

no occasion to blush, for they do not "find it fame." It would be exceedingly decorous, no doubt, if a few of these gentlemen would commit the overt act of providing such a permanent fund as Dr. Mitchell has furnished for the profession in Philadelphia, and perhaps in the end they would find such a course no greater tax upon their generosity than the one they now follow, while the profession, as is no more than right, would know to whom it was indebted, and to whom honor was due.

We all know that Dr. Mitchell has fed hysteria to good purpose, and it may be that in feeding doctors he will earn for himself an epitaph no less graceful than that of Graves, who "fed fevers." At all events, the accomplished author of "Fat and Blood" has deserved well, not only of his townsmen, but also of his brethren throughout the land; and we are quite sure that it will be recognized that not the least of his titles to their esteem and gratitude is the wise and timely act that we have chronicled.

THE PROPOSED PENNSYLVANIA ANATOMY ACT.

A BILL is now before the Pennsylvania Legislature to regulate the practical study of anatomy in the State. It has been prepared, we understand, by several of the Philadelphia teachers of anatomy. The bill provides for the creation of a Board of Distribution for furnishing unclaimed dead bodies to the several institutions that are entitled to dissecting material. The Board is to be made up of the professors of anatomy, the professors of surgery, and the demonstrators of those branches, in all the incorporated medical and dental colleges of the State, together with a representative of every non-incorporated school of anatomy or practical surgery that has, now or at the time of the appointment of such representative, not fewer than twenty-five pupils.

All public officers having charge or control of dead bodies are required to keep the Board informed in regard to the number of such bodies under their control, and the Board is to apportion the same among the educational institutions and among individuals who may desire to pursue a course of dissection by themselves. It is understood that the Board will regard the claims of the colleges as entitled to the first consideration, but in case there is no dearth of material for the schools, individuals may profit by the facilities that will undoubtedly attend the working of the proposed act. This is an exceedingly good feature in the bill, and embodies a state of things that ought to exist everywhere. It is monstrous that in this State, for instance, a man can not get possession of any material for dissection, apart from a violation of the laws, unless he betakes himself to a medical college, a course that involves not only the disarrangement of his business affairs in many instances, but perhaps the impracticability of his carrying out a special and very important course of dissection, owing to the fact that he must accommodate his own actions more or less to the purposes of the undergraduates with whom he is obliged to prosecute his work. If the Pennsylvania bill becomes a law, we trust that the Board of Distribution, although made up entirely of public teachers, and, therefore, naturally disposed to

hold college interests as paramount to all others, will not fail to see the justice and the pressing need of facilitating private dissection under all proper circumstances.

As we understand it, there is to be no price put upon bodies—no traffic in them, and their conveyance without the limits of the State is prohibited. Every college and every individual supplied by the Board is to be required to guarantee, by filing a bond in the sum of a thousand dollars, that the material is to be used only for the promotion of medical science, and within the State. The violation of those provisions of the bill that forbid traffic in dead bodies, and carrying them outside the State, is to be deemed a misdemeanor, making the offender liable to a fine of two hundred dollars and imprisonment for the term of a year.

The bill affords a reasonable prospect that, should it become a law, we shall hear no more of a scarcity of dissecting material in Pennsylvania, for it makes all the unclaimed dead bodies in the State available, whereas at present, it is stated, only the bodies of persons who have died in Philadelphia County can be claimed for dissection. Moreover, the rural authorities will be saved the expense of burying paupers, and it is to be hoped that there will be no more desecration of cemeteries.

GÄRTNER'S CANALS.

In a recent number of the "Archiv für Gynäkologie," Dr. Kocks, of Bonn, states that in a majority of cases these remnants of embryonic life, which have hitherto been supposed to persist only in a few of the lower animals, remain patulous in the human female. Chauveau ("Comparative Anatomy of the Domesticated Animals," Fleming's translation, New York, D. Appleton & Co., 1873, p. 923) says concerning them, that they are developed from the Wolffian bodies, one portion of these bodies giving rise to the development of the genital organs, and the other portion to organs of which the significance is unknown—viz., the organ of Rosenmüller, and the canals of Gärtner, the latter being present in the cow and in the sow, rarely in the mare, and never in the sheep, goat, dog, or cat. He further remarks that in the cow they exist as mucous canals which traverse the sides of the vagina for a certain distance, and then open into the vulvular cavity beside the meatus urinarius; also that their function is unknown. Dr. Garrigues, in his report to the New York Obstetrical Society, as his pathologist, upon a vaginal cyst removed by Dr. Robert Watts ("N. Y. Med. Jour.," vol. xxxiv, p. 623), which he decides to be a cyst of Gärtner's duct, quotes the author just mentioned, from the third Paris edition (1879, p. 970), to the effect that the canal extends, in the vagina of the cow, to a point six to eight centimetres beyond the os uteri. In the same paper, Dr. Garrigues states that Gärtner's duct in the male develops into the long canal which runs through the epididymis and the vas deferens, but usually disappears in women. He quotes Kölliker, who had found distinct remnants of it in the broad ligament of mature human fetuses, and Beigel, who had found it in a seven-months fetus, in the form of small epithelial tubes running toward the side, and somewhat forward in the superficial layers of the wall of the uterus. Dr. Garrigues declared his inability to find a detailed description of this organ, and a similar lack of success has attended our own search. Kocks, in the article mentioned, states that the canal or canals have not been found heretofore, excepting among ruminants and swine. From his observations, however, upon the living and the dead, he is of the opinion that

they are present in eighty per cent. of women. Their openings are at the posterior border of the orificium urethrae, on either side of it, and anterior to the hymen. By delicate manipulation they can be discovered, and a fine sound, one millimetre in thickness, can be passed to a depth of from one half to two centimetres. One or both of them may be absent, or very shallow, in certain cases. If the urethra be cut out, in the dead subject, they can be seen with the naked eye. They must not be confounded with pockets or slight excavations in the urethro-vaginal mucous membrane, which are merely chance conditions, nor should they be confounded with the shallow openings in the mucous membrane of the vestibule, between the urethra and the vagina, and in the neighborhood of the hymen, into which the glandulae mucosae vestibuli open. The analogues to these canals in the male are the ductus ejaculatorii. The canals of Gartner are not the ducts of glands, for, if they were, the glands would, of necessity, be large enough to be discovered by the finger in the anterior vaginal wall. They undergo atrophy and obliteration when similar changes occur in the generative organs.

The extent of Kocks's investigations does not appear. He states that he sought for the canals upon four dead subjects, and found them in each case; he fails to state the basis of his calculation that they are present in eighty per cent. of all cases. When we consider that pockets and excavations are very common occurrences in the urethro-vaginal mucous membrane, and in that of the vestibule, the existence of which is known to no one better than to the author in question (and, indeed, he has referred to them in his paper), we may be pardoned for being rather skeptical as to the constant, or nearly constant, existence of the canals of Gartner. This skepticism becomes more warrantable from the fact that their existence has not been ascertained by such competent observers as Waldeyer, Frey, and Kolliker. We admit, however, that their analogy to the ejaculatory ducts lends probability to the statements which have been quoted. At any rate, they are without function, as Kocks observes, and the most that can be said of them is, that they are a possible anatomical treasure-trove, which merely adds a mite to the sum of human knowledge.

ILLUSTRATED MEDICINE AND SURGERY.

This is the title of a quarterly journal, edited by Dr. George Henry Fox and Dr. Frederic R. Sturgis, of New York, and published by Mr. E. B. Treat. The first number of the second volume is now before us, and we find its contents exceedingly valuable and presented in a style worthy of the standard maintained in the preceding volume. The number contains articles with the following titles: "Dental Development," by Dr. William Hailes, Jr., of Albany; "A Case of Palato-pharyngeal Sarcoma," by Dr. Johnson Eliot, of Washington; "Excision of the Shoulder Joint," by Dr. Randolph Winslow, of Baltimore; "Three Cases of Compound Complicated Hare-Lip," by Dr. James L. Little, of New York; "Cysto-adenoma of the Thyroid Gland," by Dr. Charles Buckley, of Rochester; "Secondary Myeloid Disease of Pleura and Lung," by Dr. William Osler, of Montreal; "Congenital Union of the Fingers, with two other Cases of Malformation of the Hand," by Dr. J. H. Pooley, of Columbus, Ohio; "A Teratological Contribution," by Dr. George J. Engelmann, of St. Louis; and "Apparatus for Treating Fracture of the Patella," by Dr. J. S. Wight, of Brooklyn. These articles are all illustrated, many of them with colored drawings, a method of illustration to which particular attention is given in the journal in question, and in which it has achieved marked excellence. Indeed, for its general artistic get-up, as

well as for the intrinsic value of its contents, "Illustrated Medicine and Surgery" deserves the substantial support of the profession.

Proceedings of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of January 3, 1883.

OBSERVATIONS ON THE MANAGEMENT OF ENTERIC FEVER ACCORDING TO A PLAN BASED UPON THE SO-CALLED SPECIFIC TREATMENT.—Dr. JAMES C. WILSON read the following paper:

I desire to lay before the College a plan of managing enteric fever which I have employed during the past year, and which, tested by such uncertain but not necessarily fallacious means as are available for a limited series of cases, has yielded satisfactory results.

The object of this communication will, I believe, be best attained by first sketching in outline the plan of treatment itself, next by reviewing the considerations which led to its adoption, and finally by a brief study of the cases. This arrangement of the topics will enable us to economize time.

The Plan of Treatment.—The scope of this paper and the necessity to be brief debar me from the consideration of the general management of the patient, dietetics, the treatment of complications and sequels, and of the prophylaxis, and restrict me, in the main, to the subject of the management by medicinal means. It is, in fact, this part of the treatment that, superadded to the so-called rational and expectant method in general use in this community, differs from the common practice and constitutes the plan in question.

So soon as the patient is found to have enteric fever, or, in many instances, so soon as his symptoms warrant a reasonable suspicion that he is about to develop it, he is put to bed, ordered a diet consisting of milk, animal broths, jelly, and simple custards, in small amounts and at intervals of two or three hours. At night he is given a dose of calomel. This dose varies in amount from seven and a half to ten grains (0.5 to 0.66 gramme), and is repeated every second evening until three, or rarely four, doses have been administered in the course of the first six or eight days. It is given alone, or in connection with sodium bicarbonate. There is commonly a slight increase of diarrhoea, if it be present, without aggravation of the other symptoms, and in some instances the tendency of the temperature at this time to steadily rise appears to be controlled. If, as is frequently the case, spontaneous diarrhoea has not recurred in the first week, the calomel usually brings about two or three large evacuations on the day following its administration; not more. In either case the tendency to frequent passages in the later stages of the attack is favorably influenced by the repeated administration of this drug during the first week. If the case does not come under observation until after the tenth day, one only, or at most two doses of calomel are given. No further doses of it are, however, given during the course of the attack unless constipation occur. In this event, if the evidences of extensive or deep implication of the intestinal wall—such as abdominal pain, tenderness, or marked tympany—are absent, calomel in seven and a half grain (0.5 gramme) doses is given at intervals of three or four days. If there is reason to suspect serious intestinal lesions, the lower bowel may be more safely emptied of its contents every third or fourth day by enemata of moderate size (8 to 10 fluidounces). It is necessary to bear in mind that the gravest lesions of the gut, leading even to hæmorrhage and perforation, have occasionally been observed in cases characterized,

not only by constipation, but also by an entire absence of pain or tenderness, and very moderate tympany. The danger of salivation from calomel in these doses in enteric fever appears to be slight. In only one case in sixteen were the mercurial fetor and slight swelling of the gums observed.

Excessive diarrhoea has been controlled by the use of opium, either in suppositories containing one grain (0.06 gramme), or by the mouth in quarter-grain (0.016 gramme) doses, often associated with bismuth and given *pro re nata*. It is an invariable rule that the patient be kept in the horizontal position and to the use of the bed-pan and urinal from the time of the recognition of the disease until defervescence is completed. He is, however, turned upon his side from time to time, and made to maintain that position for twenty or thirty minutes, if necessary, being supported by the nurse.

From the beginning of the attack the following mixture is regularly administered, in doses of one, two, or even three drops in a sherry-glassful of ice-water after food, every two or three hours during the day and night:

R Tinct. iodinii, f 3 ij = 8.00 c. c.;
Acid. carbolic liq. f 3 j = 4.00 c. c.

Unless some unusual circumstance occur to render a change necessary, this medicine is not suspended until the attack draws to a close. It is well borne by the stomach, and excites no repugnance on the part of patients. In one case only has it been necessary to omit the carbolic acid on account of the disgust excited by its odor.

Partly for the sake of its favorable influence upon the skin and for the sake of cleanliness, partly because of its favorable though slight influence upon the temperature, the patient is to be sponged twice a day with equal parts of aromatic vinegar or alcohol and cold water. If it is more grateful to him, this sponging may be done with tepid water, the evaporation of an extensive film of water not below the temperature of his body probably being not wholly without a refrigerating tendency.

When the evening axillary temperature reaches 104° F. (40° C.), quinine in massive doses, 24 to 30 grains (1.66 to 2.00 grammes), is given upon a falling temperature. I usually direct 8 to 10 grains to be given in solution at 5, at 5.30, and at 6 A. M. the following morning. Administered thus at the decline of the temperature in its diurnal revolution, these large doses of quinine depress it from 2.5° to 3.5° F. (1.4° to 1.8° C.). After the lapse of forty-eight to seventy-two hours, if necessary, the dose may be repeated. If these doses be rejected by the stomach—an unusual circumstance—half the quantity of quinine may be administered hypodermically. For this purpose a citric-acid solution is to be preferred. Since the adoption of the plan of treatment under consideration, I have not encountered cases attended with such hyperpyrexia as has rendered attempts to control it by cold baths necessary or even advisable.

The minor nervous symptoms are best held in check by skillful nursing. For the relief of the headache of the first ten days, absolute quietude, a dim light, etc., are often sufficient; occasionally the bromides alone, or in combination with chloral, are required. Later in the course of the disease chloral is unsafe. From the end of the first week the patient can not be left unattended, even for a few minutes, without risk. Persons in whom delirium was only occasional and transient have, in many instances, destroyed themselves during the momentary absence of the nurse.

Alcohol is not often indicated prior to the beginning of the third week. It may, however, by reason of the habits of certain patients, be necessary throughout the attack. Although forming no essential part of the treatment, it is commonly administered in varying though usually small amounts toward the

close of the sickness. Some patients do well without taking it at all. It is, of course, administered, in accordance with well-understood indications, upon the supervention of delirium, ataxic symptoms, and the evidences of failures of the forces of the circulation. The patients are carefully watched well into convalescence, and cautioned against too soon regarding themselves as restored to health.

The dangers of the establishment of a focus of contagion are guarded against by the systematic, thorough disinfection of the stools immediately after they are voided.

The considerations which led me to adopt this plan of treatment, indicated in the foregoing sketch, are:

1. A feeling of dissatisfaction regarding the expectant method of treating enteric fever. This feeling, vague at first, grew more definite and stronger with increasing clinical opportunities, and a fuller knowledge of the natural history of the disease, until it became a motive, impelling me to cast about for some different and more satisfactory plan. This feeling has been during the past decade a very general one in the profession in all parts of the world, as is attested by an almost endless succession of journal articles setting forth new plans of treatment, and the use of new drugs in the management of this, the most common and most important of the acute infectious diseases of the present epoch in medical history. Most of the plans thus suggested have led to disappointment when tested by the fuller observations of the profession; many of them have failed to attract general attention, and some few are still *sub judice*. Their number and diversity bear witness to a widespread distrust of the once well-established expectant treatment. This distrust is, however, based upon something more tangible than a mere feeling of dissatisfaction. The statistics of all observers, whose cases have been sufficiently numerous to be trustworthy, show enteric fever to be, when treated by the expectant plan, a disease of high death-rate.

The proportion of fatal cases rarely falls below 15 per cent., and often exceeds 25 per cent., according to the hospital records of this country, Great Britain, and Continental Europe. Jacoud, with a collection of 60,000 cases, observed a mortality of 20 per cent.; Murchison, in 27,051 cases, 17.45 per cent.; Liebermeister, in 1,718 cases, at Basle, under an expectant plan, records 27.3 per cent. of deaths. But, turning from broad generalizations to personal experience, who is there here that, many times elated by the happy issue of mild or average cases treated by the expectant plan, has not realized the sense of utter powerlessness attending it when he has stood face to face with cases in which *to do* rather than *to wait* has been necessary to save life.

2. Enteric fever is the very type of the general diseases, of affections *totius substantiæ*. The tissues are universally implicated in the morbid processes; no function of the body wholly escapes perturbation. For this reason plans of treatment suggested by the prominence of certain groups of symptoms, or by the known lesions of particular organs, even though of undoubted benefit as far as they go, are in theory unsatisfactory, because they are directed in effect against conspicuous manifestations of the cause of the sickness rather than against the cause itself.

While in actual practice the treatment by turpentine, by alcohol, by opium with lead, or the silver nitrate, or by agents capable of controlling the febrile movement, as quinine, digitalis, salicin, and the salicylates, even the cold-water treatment itself, although at times and in the hands of certain clinicians showing favorable results—all these have failed of general acceptance on the part of the profession.

3. The general character of the disease, the specific nature of its cause, the unsatisfactory results alike of an expectant and

of a symptomatic plan of treatment, or rather of the two combined, have united to render the idea of a specific treatment, a true cure for enteric fever, a most attractive one, to stimulate thoughtful observers to renew again and again the disappointing search for it. To this idea may be traced the treatment by the mineral acids, by chlorine-water, by carbolic acid, by quinine alone, by quinine and digitalis, by iodine, by the potassium iodide, by calomel.

4. Not only is the conception of a specific treatment for specific diseases a most attractive one, and the attainment of such a treatment for enteric fever brought within the bounds of a reasonable hope by the analogy of syphilis and the malarial diseases, but the search after it with due caution and judgment has also the warrant of the very highest medical authority.

Passing by some earlier names, I refer to Da Costa, who has said: "It would be as illogical as absurd to suppose that we shall never possess the coveted means really to cure the continued fevers. Doubtless to the physicians of the time of Charles V the radical and specific treatment of the malarial fevers appeared as hopeless and remote as the radical and specific treatment of the continued fevers appears to the scientific inquirer of our day."

I refer also to Liebermeister, who, treating about eight hundred cases, part with calomel, part with iodine, had with the former drug a mortality of only 11.7 per cent., with the latter of 14.6 per cent., against 18.3 per cent. for cases treated without those remedies, but in other respects upon a similar plan.

Bartholow has also spoken in favorable terms of the treatment by iodine in combination with carbolic acid.

The treatment adopted is thus seen to consist of the use of the two remedies that are proved to exert a favorable influence upon the disease, iodine and calomel, with the addition of carbolic acid in minute amounts. I am aware that no positive conclusions as to the efficacy of particular plans of treatment can be deduced from a limited series of cases. I am also aware that few acute diseases show greater variations in intensity and in the percentage of mortality at different periods, and under different circumstances, than enteric fever. Nevertheless, I have ventured to occupy your attention with this subject to-night because the results of the treatment encourage me to hope that its discussion in this way will lead to its trial on a more extended scale. That it amounts to a specific treatment in the narrow sense is not affirmed. It is tentative, provisional, but it is nevertheless to be regarded as a contribution to the subject of the specific treatment of enteric fever.

The total number of cases treated by this plan is sixteen; all recovered, one being now in the second week of convalescence.

Of these, eight were severe, the temperature reaching or exceeding 104° F. (40° C.).

Of these eight severe cases, one was characterized by uncontrollable vomiting in the third week. The patient retained no food taken by the mouth for five consecutive days.

One case was very irregular in its course, and was complicated by an obscure abdominal abscess which discharged by the bowel. The temperature in this case on two occasions attained 105° F. (40.5° C.). This case presented the characteristic eruption of enteric fever.

A third case was prolonged by a severe relapse.

Of the eight cases in which the observed temperature did not at any time attain 104° F. (40° C.), and which were therefore looked upon as medium or mild cases, one was complicated by crural phlebitis, and another by the occurrence of intestinal hemorrhage.

The average duration of the eight severe cases was about thirty-one days; that of the eight mild and medium cases was about twenty-five days.

Of the whole number, ten were treated in hospital, six in private practice. All, from the first, were under my personal care.

In two cases the special plan of treatment was abandoned about the beginning of the third week on account of the super-vention of unusual symptoms of great gravity. These related, respectively, to gastric irritability, and an obscure abdominal abscess.

These sixteen cases are, unfortunately, not a consecutive series. During the year in which I have had the opportunity of observing them, two other cases of enteric fever have occurred in my hospital practice in which this plan of treatment was not employed. One was that of a man suffering from rheumatism, who, after a stay of several weeks in the wards, and in a bed near that occupied by a patient very ill of enteric fever, was observed to be febrile, and to have the typhoid eruption. This person, previously greatly reduced, was not regarded as a suitable subject for a special treatment, the efficacy of which was not yet established in my mind. The other was a man who, with an obscure history of a sickness of many weeks, and a very irregular temperature, developed the typhoid eruption, and within forty-eight hours had general peritonitis. These two fatal cases have, however, no bearing upon the result of the treatment.

In private practice several cases of mild continued fever of long duration were treated upon this plan during the past winter. I believe them to have been anomalous cases of enteric fever, but, as the rose spots of that disease were absent, and their departure from the typical disease was wide, I have not included them in the above collection of cases treated. They all recovered.

The result of this plan of treatment has not only been satisfactory in respect of the recovery of all the cases treated, an accidental circumstance not liable to mislead persons familiar with the disease, but it has also been satisfactory in respect of the general course of the attack, and the appearance of the patient. These were in the main, despite the severe type of the disease in several of the cases, and despite the occurrence of grave complications, favorable. I make this statement with due regard to the personal equation, and with no willingness to permit the observed fact to differ from the actual fact, for I desire any who may make trial of this plan to be more favorably impressed with the results of it than they have been impressed with my account of it.

Dr. GEORGE HAMILTON spoke of the great importance of preventing hypostatic congestion by changing the position of the patient from time to time. This was one feature of the plan of treatment recommended some time ago by Dr. William Pepper, in typhoid fever, by which he obtained the unequalled result of 98 per cent. of recoveries. He was not, however, at this time able to recall in detail the method of treatment.

Dr. J. T. ESKRIDGE stated that the treatment to which Dr. Hamilton referred consisted in the administration of nitrate of silver, and was that which had been introduced by the late Dr. J. K. Mitchell some years ago.

Dr. ROBERTS BARTHOLOW said that the plan of treatment of typhoid, advocated in the very interesting and able paper just read, is, as all present probably know, in part, the so-called "specific" method. The administration of calomel in full purgative doses during the first week serves a double purpose: it has an effect on the range of temperature, and it acts on the typhoid germs present and multiplying in the intestinal canal. The use of iodine—usually Lugol's solution—throughout the disease, is also one mode of the specific treatment. By the use of this medicine, it is attempted to prevent the multiplication of germs in the intestine, to check fermentation, and to maintain an antiseptic action in the blood.

Although the existence of typhoid germs has not been proved, it must be regarded as possible. Klein, a few years ago, announced the discovery of the specific organism of typhoid in the affected intestinal glands, but Creighton, of Cambridge, showed that the supposed germs were produced by the mode of preparation. This *fiasco* threw great discredit on the whole question of germs. Nevertheless, the course of treatment directed against supposed germs—the antiseptic method—has had a most favorable influence on the progress and mortality from typhoid. While the specific plan has been advocated in Germany, the Montpellier school have brought forward carbolic acid as the remedy, and the success which has attended the use of this remedy has been really remarkable. Quite a different complexion has been put on the statistics of mortality since they began the use of carbolic acid. It is probable that the combination of carbolic acid and iodine gives better results than the use of either singly. According to my observation, this method of treatment diminishes the diarrhoea, lowers the fever, and renders the disease much less violent, consequently lessening the mortality. Dr. Wilson has, therefore, rendered us a real service by drawing attention anew to this plan of medication, and especially by supporting his position with valuable cases and statistics. Besides this use of medicines, Dr. Wilson's treatment contains many valuable suggestions and practical methods, which, no doubt, contribute materially to his success.

Dr. J. M. Da Costa spoke of the purgative treatment in enteric fever as that which had been tried in the French hospitals and for a time sanctioned by Louis. As regards calomel, it was partly by its purgative action that it was supposed to be beneficial. In his hands the calomel treatment had not yielded favorable results. He had found carbolic acid useful in controlling diarrhoea and in lowering the temperature. He had also employed thymol in one-half to one-grain doses. He suggested the use of this remedy in the place of carbolic acid, as more acceptable to the stomach.

Dr. Wilson, in reply to the question of Dr. Hamilton, said that he considered it necessary to frequently change the position of the patient to prevent pulmonary hypostasis. He had intended to emphasize this point in his paper. He called attention to the fact that carbolic acid and like drugs probably exert a favorable influence upon the course of enteric fever by their power to stay the rapid decomposition of the intestinal contents, which, for lack of the antiseptic influence of the intestinal juices, the bile, etc., all of which are changed, is a secondary cause of irritation, diarrhoea, and tympany. Calomel, also, he thought, probably exerted an indirect beneficial influence in the same direction.

HEART-PUNCTURE AND HEART-SUTURE AS THERAPEUTIC PROCEDURES.—Dr. JOHN B. ROBERTS read a paper on this subject as follows:

It is more than probable that, in a few years, puncture of the heart-wall (cardicentesis), with direct abstraction of blood by aspiration, will be recognized as the best treatment in cases of greatly dilated or much distended right heart, with intense pulmonary engorgement; and that incision of the pericardium with suture of the heart muscle will be accepted as proper in cardiac wounds. Hence, these latest novelties in cardiac surgery deserve the attention of the Fellows of the College.

That punctures of the heart are comparatively harmless has been well known to many for some years. In 1872, Roger, while performing pericardicentesis on a child with pericardial effusion, thrust the needle into the right ventricle and withdrew about 64 Troy ounces (200 grammes) of pure venous blood. The boy, who was aged five years, became pale, sweated, and had an imperceptible pulse. The withdrawal of the pericardial fluid, accomplished prior to the heart injury, was beneficial; and the

cardiac puncture did no permanent mischief, for the patient recovered. Death occurred five months later from long-existing dilatation and valvular disease of the heart ("Bull. de l'académie de médecine," 1875, p. 1276).

In Hulke's case ("Trans. of the Clinical Society of London," viii, p. 169), a woman with pleuro-pneumonia was supposed to have large pericardial effusion, and a trocar was introduced through the fourth left intercostal space. Nothing escaped except a drachm of venous blood, after which the patient seemed relieved of dyspnoea. She died four weeks later from a complication of diseases, and the autopsy revealed cardiac dilatation and valvular changes.

I have said elsewhere ("Paracentesis of the Pericardium," 8vo, Philadelphia, 1880), in commenting upon this case: "The abstraction of blood seemed to relieve the distended heart much better than phlebotomy would have done, as was evinced by the diminution of threatening symptoms and the decrease of the area of dullness."

Cloquet, Bouchut, Legros, and Onimus have also observed the apparent innocuousness of wounds of the heart made by capillary trocars. Steiner found, ten years or more ago, that electro-puncture needles could be quite safely introduced into either ventricle, provided they were at once withdrawn ("Med. Times and Gazette," May, 1873, p. 492, from Langenbeck's "Archiv für klin. Chirurgie").

It has been considered less safe to puncture the auricles; but the interesting paper of Dr. Benjamin F. Westbrook, just published in the "Medical Record" for December 23, 1882, seems to show that our fears are as unfounded as were those of our predecessors in regard to ventricular puncture. It is, in truth, to call attention to his case of harmless *intentional* cardicentesis and to his researches in the surgical anatomy of the operation that I have been led to refer to the corroborative evidence of the cases mentioned above.

I have with much satisfaction, as have many others, done venesection at the bend of the arm for the temporary relief of the distressing symptoms of dilated heart, and for the dyspnoea due to the pulmonary engorgement of acute pneumonia. If, however, a few *drachms* of blood drawn directly from the heart give the relief that could only be afforded by taking a similar number of *ounces* from the veins of the arm, it seems proper to adopt the former measure. The subsequent circulatory depression from anaemia would undoubtedly be less than after the latter operation.

It is manifestly necessary, however, to determine that cardicentesis is innocuous before it can take the place of venesection. The above-mentioned cases and Dr. Westbrook's experience tend to show that such is the fact.

Dr. Westbrook believes that the proper place to perform the operation is in the third costal interspace close to the *right* edge of the sternum. This situation enables the operator to tap the right auricle without injuring the right internal mammary vessels, and with little danger of striking the tricuspid valve. My own preference would be to perforate the ventricle of the right heart by introducing the needle through the fourth interspace, about one and a half or two inches to the *left* of the median line of the sternum. Dr. Westbrook's opinion, however, is entitled to more deference than mine, because he has studied the subject with special reference to cardicentesis, while my special investigations have been limited to the consideration of pericardicentesis.

Further experimentation in heart-puncture for the relief of cardiac distension and pulmonary engorgement is requisite, but it is probable that it will soon become a well-recognized surgical procedure in selected cases. Pericardicentesis has already taken that position, and there is no reason to believe that cardiac

surgery will stop its march with the demonstration that the pericardium can be treated as the pleura.

In October, 1881, I read a paper before the Anatomical and Surgical Society of Brooklyn ("The Surgery of the Pericardium"; "Annals of Anatomy and Surgery," December, 1881), in which I advised resection of costal cartilage and incision of the pericardium for removal of foreign bodies in the pericardial sac; and at the same time said: "The time may possibly come when wounds of the heart itself will be treated by pericardial incision, to allow extraction of clots, and perhaps to suture the cardiac muscle."

It seems as if this time had now almost arrived, for Dr. Block has not only expressed a belief that death can be averted in many cases of heart-wounds by simple incision of the pericardium to allow escape or extraction of the clots which cause pressure and death, but has also undertaken to demonstrate by vivisectional experiments that suture of the heart is a simple operation, and requires but three or four minutes ("Am. Jour. of the Med. Sci.," Jan., 1883, p. 276; from "Journal de méd. de Paris," Oct. 28, 1882; from "Gaz. méd. de Strasbourg," Oct. 18, 1882). He finds that opening of the right and left ventricles, and entire compression of the heart for the application of sutures, can be supported by rabbits for several minutes. During suturing he seizes the apex of the heart and draws the organ forward until the traction prevents the escape of blood from the wound. Sutures are then introduced, or the orifice closed by ligation. Even if cardiac pulsation and the respiration stop during this mechanical interference with the heart's movement, death, he asserts, does not necessarily ensue.

These experiments are even more important than the researches spoken of in regard to heart-puncture. I regret that as yet I have not been able to consult Dr. Block's original memoir, but I hope at a future time to do so, and perhaps to be able to report some investigations of my own which I desire to make in the same direction.

The annual reports of the standing committees were then presented.

The Publication Committee reported a larger contribution of interesting papers to the forthcoming volume of "Transactions" than has ever been made before.

The Library Committee reported that the library contains 28,653 volumes, of which 15,901 belong to the general library, 6,208 to the "Lewis Library," and 1,544 are duplicates. During the year 1882, the additions to the library amounted to 1,234 volumes. A complete card catalogue of authors and subjects has been made of the "Lewis Library," and that of the general library is well advanced. The library of the late Dr. H. Lenox Hodge, containing 1,665 volumes, is deposited with the College in trust. The constant and rapid growth of the library obliged the committee to urge a liberal appropriation for the extension of the shelf room and the payment of the librarian and the assistant charged with preparing the catalogue. Next to the library of the Surgeon-General's office, that of the College of Physicians of Philadelphia is the largest medical library in the United States.

The Mütter Museum Committee urged the necessity of providing increased accommodation for the museum.

During the last year a large number of valuable preparations have been received:

From Framond, of Paris, 100 wax specimens illustrating diseases of the eye; 22 preparations (natural) showing dentition from early life to old age; 20 casts of female pelvis taken from noted cases of deformity; 1 large wax model of thoracic duct and lymphatics; 2 rubber models of pelvic viscera, male and female; 1 wax preparation of confluent small-pox; 1 wax preparation of syphilitic disease of scalp; 4 natural lymphatic injections

of foot, hand, and stomach, also an injection of the canal of Fontana; and 1 adult skeleton, mounted at Royal College of Surgeons, London.

They have also received from Rohon, of Vienna, six mounted skeletons, illustrating stages in development, with known age and history to each.

They have procured and had mounted the skeleton of a noted case of hydrocephalus.

Also, through Dr. Hays, the committee obtained the body of a cyclops, which was dissected and reported upon by Drs. R. Meade Smith and A. J. Parker (see "American Journal of the Medical Sciences" for July, 1882). A good plaster cast and two drawings were made from it. Other preparations of importance were also received.

The Committee on the Directory for Nurses reported that the Directory was opened May 15, 1882. Rooms for the secretary were fitted up, and the telephone and telegraph introduced. Circulars and blanks to the number of 8,500 were prepared and widely distributed to all the physicians in Pennsylvania, New Jersey, and Delaware, and to the summer hotels within easy reach of this city. The co-operation of the two training-schools for nurses (the oldest two in the country) was secured, and the medical and daily press of the city showed a very friendly spirit, and assisted us in making the Directory known. The following are the rates of charge adopted: For information leading to the engagement of a nurse between 7 A. M. and 6 P. M., one dollar; between 6 P. M. and 10 P. M., two dollars; between 10 P. M. and 6 A. M., three dollars; for wet nurses, uncertified, five dollars; for wet nurses, certified (after careful medical examination of mother and child), ten dollars; for finding and sending a nurse, an additional dollar. Up to December 1st, the number of applications for registration has been 296. Fully registered, 214; approved and awaiting registration, 17; disapproved, 19; stricken from the roll for grave faults or defects, 2. Of the registered nurses there are 26 males and 187 females; 35 graduates of training schools; 165 non-graduates; manipulators, male and female, 11; cuppers and leechers, 3.

The number of calls for nurses has been 342 during the seven months, an average of about 50 a month. We have furnished as many as 8 in a day, and 5 to a single family. One of the most important results achieved through the Directory is the promptness with which calls to grave emergencies are met. Another and very marked advantage of the Directory is, that we not only give information as to disengaged nurses, but, if desired, will find and send them to the patient. This saving of time and trouble to applicants is often very desirable, and the small extra fee charged for the service (one dollar) is very gladly paid. Especially is this service valuable to patients out of the city.

We have also undertaken to supply wet nurses. We have had 35 applications, but have only been able to supply 13, and we beg especial attention to this fact, in order to obtain many more of this class of nurses.

Our expenses have exceeded our income by a very large amount, and had it not been for the generous contributions of many friends, chiefly through Mrs. Weir Mitchell, the Directory could not have been placed on a firm foundation at its start. Next year it is hoped that it will be about self-supporting.

"PUNCH" ON OLIVER WENDELL HOLMES.—"Punch" thus addresses Dr. Holmes on his returning from the chair of anatomy in Harvard:

"Your health, dear 'Autocrat!' All England owns
Your instrument's the bone and not the Bones;
Yet hear our wishes—trust as they're not cold ones!
That, though you give up bones, you may make old ones."

Reports on the Progress of Medicine.

QUARTERLY REPORT ON DERMATOLOGY, SYPHILOGRAPHY, AND GENITO-URINARY DISEASES.

No. XIII.

By EDWARD BENNET BRONSON, M.D.

THE CONTAGIOUSNESS OF LEPROSY.—Dr. J. C. White, of Boston, after an able and thorough-going review of the question of contagion in leprosy (*"Am. Jour. of the Med. Sci.,"* Oct., 1882), arrives at an affirmative conclusion, in accordance with which he urges certain public measures of prophylaxis. He advises "the establishment of graded hospitals, if possible, in insular localities in various parts of the country, to which all access should be prevented excepting under restrictions determined by professional rules; the enactment of laws which should make residence compulsory and perpetual, and the concealment of the disease punishable by severe penalties." These laws should apply equally to sporadic, to endemic, and to imported cases, though in the case of foreigners the option should be given of a return to their own land. It is also advised that the importation of lepers be prohibited. Dr. White avows his belief in the "bacillus lepræ" of Hansen, Neisser, Koch, Koebner, Cornil, Berman, and others, regarding it as the essential cause of the disease.

On the other hand, Schmidt, in a recent paper (*"Chicago Med. Jour. and Exam.,"* April, 1882), took decidedly the opposite view. In the specimens which he examined he was unable to find any bacteria in the interior of the tissues. He found the micrococcus zoöglea described by other investigators, in his sections, but always upon the surface, where he believed they had lodged after removal from the body.

LEPROSY AMONG THE ZULUS.—Merensky (*"Arch. f. path. Anat. u. Physiol. u. f. klin. Med.,"* lxxxix, 1, 1882), in traveling through Southern Africa, made some interesting observations of the leprosy that prevails among certain of the Zulu tribes. In one tribe he examined six lepers with a view to ascertaining the etiology of the disease. In this instance the origin of the epidemic appeared to be clearly traceable to an individual who had entered the tribe (coming from another region) some twenty years before. This individual had leprosy, and was the first case of the disease that had ever been seen in the tribe. All the cases which had occurred subsequently were in persons more or less directly connected with him by marriage and otherwise. It is stated that leprosy prevails in a number of the Zulu tribes inhabiting the region of the Drakenberg Mountains. The Zulus in these parts generally regard it as contagious. The name they give to it, on account of the spots that appear, is "ubadeka," from "ukubadeka," which by an euphemism might be translated "with ordure soiled" (*"mit Koth bewerfen,"* according to Merensky).

RODENT ULCER.—There has always been more or less uncertainty regarding the relations of this disease to epithelioma. It has been recently stated by Sangster (*"Brit. Med. Jour.,"* Oct. 21, 1882) that two very marked factors in the pathological anatomy of the latter disease are in rodent ulcer "conspicuous by their absence." In epithelioma there is a very characteristic activity of the Malpighian layer. The inter-papillary portions form prolongations that dip down farther and farther into the tissues. The other factor is the production of the well-known cell-nests, or "globes epidermiques." In five cases of rodent ulcer which Sangster submitted to careful microscopical examination, neither of these two phenomena appeared. The rete was usually thin and attenuated, never attaining any greater thickness

than in any chronic inflammatory process. In only two of the five cases was there anything like cell-nests, and those were not well marked. Evidence was discovered, however, of connection of the disease with the hair follicles. There were decided out-growths from the external root-sheaths. Reference is made to certain "cell-masses, with peripheral, columnar, and vertically placed cells very similar to those seen in molluscum," which Virchow had shown to be connected with the hair follicles.

CHRYSORHINIC ACID INTERNALLY FOR PSORIASIS.—In a recent communication to the *"Lancet,"* Canty reported three cases of psoriasis treated by the internal administration of chrysorubin without noticeable effect upon the cutaneous disease. In one case the dose was increased to one grain and a half three times a day, but it was not tolerated. The opinion is expressed that, in the cases previously reported where this method of treatment had been successful, the improvement was due to the continuous purging, and that some other cathartic would have accomplished the same result and with less disagreeable consequences. Canty is of the opinion that any internal remedy that benefits psoriasis must improve the quality of the pulse, making the rather positive statement that "no case of this disease occurs in which the pulse is not either slower, smaller, or weaker than it ought to be, and any medicine which either ameliorates or cures this disease improves the pulse in either rapidity, volume, or strength"—a statement that we do not remember to have met with before.

ICHTHYOL.—In a late number (Dec., 1882) of the *"Monatshefte für praktische Dermatologie"* are two contributions—one by Rudolf Schröter, the other by Unna—relating to a new remedy for skin diseases. The article by Schröter relates the history of its discovery and describes the method of its preparation, while Unna gives an account of how it is employed and of its effects upon diseases of the skin.

Ichthyol is an oily product obtained from a peculiar bituminous mineral found in the region of Seefeld in the Tyrol. The mineral occurs in beds or veins of varying thickness, lying in fossiliferous rock, which bears numerous fish-prints, together with a certain number of petrified fishes. It has been surmised that the bitumen owed its origin to the animal residue of fishes and other marine animals left there in prehistoric times, when the region was still submerged by the sea. Hence the name "ichthyol." To obtain the oil, the bituminous rock is first subjected to a dry distillation in iron retorts. The fluid product that results soon separates spontaneously into a thick, tarry substance, and a very fluid, dark-colored, strong-smelling oil. The latter is then subjected to the action of concentrated sulphuric acid and various other chemical processes, by means of which it is clarified and refined, when a neutral or slightly alkaline product results, having a peculiar odor described as "kräuterartig" (herb-like). This product, which is what is known as ichthyol, is regarded as an extract from the original oil. Its chief ingredient is said to be a sulphur acid. Sulphur forms from two and a half to ten per cent. (according to the method of preparation) of its composition. In appearance it is of a somewhat tarry character, but resembles none of the ordinary tars either in its odor or in its chemical composition. Its consistency is about the same as that of vaseline. It forms an emulsion with water, and is miscible in any proportions with oils or vaseline. It is partly soluble in alcohol and partly in ether; wholly so in a mixture of both.

Unna maintains that the efficacy of ichthyol as a topical agent in skin disease—and this efficacy he has found to be very considerable—is chiefly due to the sulphur which it contains. He regards the drug as essentially an artificial production, and refers to the fact that the chemical treatment by which it is produced increases the proportion of sulphur from two or three

per cent. to about ten per cent. Moreover, there is a marked increase by this same means in the proportion of oxygen. He considers ichthyol as resembling a ten-per-cent. sulphur ointment, but differing from the latter in that the sulphur is in a very intimate chemical union with the other ingredients.

Unna made his first trial of the drug in a case of universal psoriasis. One arm was treated with chrysarobin, the other with ichthyol. At first the latter appeared to be having the most rapid effect, but afterward, when the chrysarobin had fairly begun to act, the ichthyol was shown to be so decidedly inferior that it was abandoned entirely, and the chrysarobin was applied to both sides. But it was discovered that ichthyol, though applied for a long time continuously, even in its purity, to the skin never caused any signs of eczema, as would invariably be the case were a ten-per-cent. sulphur ointment applied in the same way. This led to the employment of the new remedy in eczema. Unna refers to thirty cases that he has treated with ichthyol with very decided success. The eczemas treated were of many varieties—both moist and dry, papular, squamous, circumscribed, and diffuse, and were confined to no particular region of the body. The drug was employed in the form of a salve, varying in strength from five to ten, fifteen, and twenty per cent.; also it was used pure or in the form of spray from a solution in alcohol and ether. The pure form is not recommended, however, but a fifty- or forty-per-cent. solution in vaseline or lard is preferred for adults, while from ten to two per cent. is considered strong enough for children.

It is advised that, commencing with an ointment moderately strong, the strength be gradually decreased as the case improves, since otherwise the ointment, after a time, tends to retard the progress of the cure. Moreover, the condition of the cuticle is said to afford a criterion for the strength of the application. For example: if in a papular eczema a fifty-per-cent. ichthyol salve answers the purpose, in a moist, abraded eczema a strength of not over twenty or thirty per cent. will be required. In general, the more intact and the thicker the cuticle, the stronger must be the ointment. The chief virtues of ichthyol are stated to be as follows:

First, it tends largely to relieve smarting and itching, combining the good qualities of both Hebra's (diachylon) and Wilson's (zinc oxide) ointments on the one hand, and those of carbolic acid and tar on the other.

Second, it offers this advantage over all other sulphur preparations, namely: that it may be combined with lead and mercurials without any separation of sulphur taking place.

The following combination is recommended:

R Lithargyri	10.
Coq. c. aceti	30.
Adde	
Olei olive, adipis, aa.	10.
Ichthyol.	10.
M., ft. ung.	

Inasmuch as this ointment forms an emulsion with water, it is very easily removed from the skin. The disagreeable odor of the ichthyol has not yet been overcome.

Aside from eczema, Unna is of the opinion that the new remedy will be found valuable in all cases where sulphur preparations have heretofore proved themselves valuable. With reference to the internal exhibition of ichthyol there have been as yet no satisfactory investigations.

NERVE-ENDINGS IN THE EPIDERMIS.—That the cutaneous nerves do not all stop at the epidermis has long been well known. It was first demonstrated in lower animals that many nervous filaments penetrated the epidermis, where they terminate in club-shaped extremities. Similar facts were afterward shown

to obtain in the case of the human skin. But quite recent investigations have revealed a nervous distribution in the epidermis of an extent far beyond anything suspected before. Pfitzner described ("Morphol. Jahrb.," Bd. vii, p. 726) nerves in the epidermis of the larvæ of the frog and salamander, at a certain period of development, that terminated after penetrating the cell-wall of each prickle cell, with small bulbous extremities near the nucleus. Every cell contained two of these terminal filaments. Afterward the same observation was made by Pfitzner in the epidermis of the human subject.

Unna, pursuing this line of investigation, has recently ("Monatsh. f. prakt. Dermatol.," Oct., 1882) fully corroborated Pfitzner's results. His paper is accompanied with photographs, in which the appearances are very clearly exhibited. A striking feature of the appearance is the invariable association in every cell of the terminal bulbs in pairs. They did not appear to be branches of one twig, but usually approached the cell from different directions. These researches, revealing as they do such a surprising organization of the nervous system in the epidermis, will doubtless be found to have very important bearings both upon the physiology and pathology of the skin.

THE UPLANDS MANIFESTATIONS OF PALUDISM.—In a paper on this subject by Verneuil and Merklen ("Ann. de dermat. et de syphil.," Nov., 1882), the following are the conclusions arrived at:

1. Herpes is one of the common manifestations of malarial disease.

2. It may either precede the paroxysm of intermittens, or occur during any one of the three stages of the paroxysm, or it may follow the stage of sweating. It may appear even after the paroxysms of the fever have been suppressed by means of sulphate of quinine. There is no etiological connection between the herpes and the fever, notwithstanding their frequent coincidence.

3. Paludic herpes does not present any peculiar features. Its most common locations are the face, the region about the lips and nostrils, the eyelids, the cornea, and such points as are most abundantly supplied with nerves. Though ordinarily discrete, in certain epidemics the eruption presents a remarkable tendency to confluence.

4. Black crusts, or, more especially, black vesicles attending the herpes, pertain to grave and pernicious forms of malarial fever.

5. Exceptionally, the herpes of malaria takes the form of zoster.

6. The ordinary forms of malarial herpes may be preceded by and accompanied with vaso-motor disturbances upon the surface of the skin and disorders of sensibility.

It is believed, in consideration of the habitual locations of the eruption, of its concomitant disorders, of its possible appearance in the absence of a febrile attack, that the cause of the disease is referable to a nervous lesion, perhaps to a congestion of the cutaneous nerve-branches, resulting from the localization of the malarial poison in these nerves.

SALICYLATE OF SODIUM FOR LEPTODYMITIS.—Dr. Henderson, of Shanghai, relates the histories of three cases of epididymitis treated with apparently remarkable effect by salicylate of sodium ("Lancet," Dec. 16, 1882). The treatment was suggested by the speedy relief afforded by this drug in acute articular rheumatism. In all the three cases the inflammation was of a high grade, and attended with considerable fever. The remedy was given in 20-grain doses, repeated at intervals varying from one to three hours. It is advised that it be repeated hourly till at least three doses have been taken, and that it should only be employed in cases of decidedly acute character, as evinced by a distinct rise in temperature.

The well-known effects of salicylic acid and its salts as vas-

cular sedatives furnish a very fair *rationale* of the results the writer reports, and entitle his experience to further consideration. Our anticipations, however, would be more sanguine but for the indifferent success that has attended the trial of certain other remedies vaunted as speedy cures for orchitis.

Letters to the Editor.

STATEMENTS CONCERNING THE NEW CODE.

BROOKLYN, March 7, 1883.

To the Editor of the New York Medical Journal:

SIR: I have just noticed a letter in the number of your journal for January 13th, signed "Truth" and headed "Misstatements concerning the New York Code." Anonymous communications are entitled to but little consideration, but this one reiterates unwarrantable statements which have been made so often in the editorial columns of the medical press and in oral discussions, that it seems proper they should be corrected.

"Truth" denies that the report of the Committee on the Code of Ethics "was sprung on the society without notice." "The facts are," he says, "that the report of the committee was printed in advance of the meeting, and a copy was furnished to each member in attendance prior to the session at which it was acted upon, thus permitting all to thoroughly acquaint themselves with its nature." This statement, unintentionally I hope, gives a false impression. A fair interpretation of the statement implies that the report was printed and distributed to the delegates and permanent members of the State Society some time prior to the meeting at which it was acted upon, "thus permitting all to thoroughly acquaint themselves with its nature." The real fact was that the nature of the new code, as prepared by the Revisionary Committee, was unknown, except to the committee and three or four others, until it was sprung upon the members just before the meeting began.

"Three or four days before the session of 1882 the writer received from a member of the committee a copy of their printed report, with an injunction to keep it strictly private, as it had been shown to only two or three persons outside of the committee" ("Ephemeris," January, 1883). The writer of this letter secured a copy of the new code at the same time, with the same injunction of secrecy, from a valued friend, a member of the committee. What this extreme privacy meant is known only to the committee, and they have made no explanation of it. I have been informed by many prominent members of the society that they were ignorant of the matter until the report was presented and pressed upon the society for immediate action; that, had they known the committee proposed in their report to emasculate the code, instead of following the instructions of the society to revise it, they would have been present at any sacrifice, and the code question would not now be agitating us, for the vote at the meeting this year indicates that the proposed change would have been defeated at the previous meeting.

Your correspondent "Truth" is greatly disturbed that a "manufacturing pharmacist" should be one of the prominent objectors to the new code. It is not a little surprising that Dr. Squibb's stalwart, logical, and temperate defense of the life and honor of the profession has only been met by innuendoes unbecoming members of an honorable profession. Although he is not now an active practitioner of medicine, he has adopted pharmacy as a medical specialty, and his opinions are, to say the least, entitled to as much consideration on all questions concerning the medical profession as those of any specialist in diseases of the eye, the ear, the skin, or syphilis, and it is known to his more intimate associates that no man among us is so frequently consulted in questions of therapeutics by physicians in all parts of the country. Beginning his professional life as a Demonstrator of Anatomy and Clinical Assistant to the late Professors Meigs and Mütter, in the Jefferson Medical College, in which positions he distinguished himself, he subsequently entered the navy, high on the list, and, during his more than ten years' service, contributed to the journals valuable papers upon medical and surgical subjects. In the city where he resides he is not a mere "manufacturing pharmacist," but is frequently invited to act as a consultant in important medical and surgical cases by the most eminent practitioners among us. You have truly said, Mr. Editor, that "Dr. Squibb's devotion to the interests of the profession and his knowledge of what those interests involve are not exceeded by those of any other man."

Away with such puerile personalities, my new-code friends. They are "unworthy a physician and a gentleman." Seek more logical—I had almost said more honorable—methods for counteracting the influence of a man whom even his opponents delight to honor, than by mud-slinging. His friends must not allow him to be misinterpreted, whether their action be grateful to him or not.

I must beg your pardon, Mr. Editor, and his, for noticing these contemptuous flings.

"To gild refined gold, to paint the lily, . . .
Is wasteful and ridiculous excess."

JOS. C. HUTCHISON.

THE NEW YORK INFANT ASYLUM.

NEW YORK CITY, March 6, 1883.

To the Editor of the New York Medical Journal:

SIR: Will you kindly publish the following statement of facts and oblige the undersigned:

The New York Infant Asylum was incorporated as a founding house, by act of Legislature, in 1865. Its charter was amended in 1872, for the purpose of allowing the Board of Managers "to provide such lying-in wards and methods of care and guidance as shall tend to prevent the maternal abandonment of homeless infants, and diminish the moral dangers and personal sufferings to which homeless mothers are exposed."

The Maternity Department is open only to needy women of the city and county of New York, of previously good character.

The Board of Managers has for many years intrusted the sanitary and medical care of the inmates to a "Medical Committee," constituted

in accordance with Section V, Article III, of the By-Laws, viz.: "The Medical Committee shall consist of the *Medical Members of the Board*, whose duty it shall be to exercise a careful supervision over the sanitary condition of the Asylum, including all matters pertaining to the health of the inmates."

The results of the work of this committee have been regarded, year by year, by the Board of Managers, as creditable both to the Asylum and to the committee.

The President, Mr. Clark Bell, in the annual address in January, 1880, says: "The Medical Department is in excellent shape, and the results show how well and ably the medical gentlemen have discharged their duty, and how much the welfare of the inmates is indebted to their self-sacrificing labors." In the annual address in January, 1881, the President says: "The Medical Department is still in substantially the same hands, and the results of the last year may properly be considered as the best possible testimony to the excellence of this department." In January, 1882, the President states, in the annual address, that "The Medical Department is still in substantially the same hands. . . . The analysis of these reports (the medical reports of the various branches) shows that the death-rate of this institution still continues to be below that of any similar institution in the world, so far as it has come to the knowledge of your officers."

The medical statistics for the year 1882 are as favorable as those of any previous year, and the results of the work of the Medical Committee for that year would have warranted upon the part of the President a statement similar to those made in the annual addresses quoted above.

At the annual meeting of the Board of Managers, held in January last, however, the President (having already, by an unusual method of procedure, added ten new names to the list of managers, which for a long time had contained only nineteen names) recommended that Section V, Article III, of the By-Laws (cited above) be amended, so that any five physicians whom the Board should designate should become the Medical Committee. This amendment was passed, in direct violation of the provision of the By-Laws regulating amendments, notwithstanding the protests of members.

Then the following resolutions were offered, viz.:

"Resolved, As the sense of this Board, that the interests of the Asylum require a revision and reorganization of the Medical Department; that visiting and consulting physicians should be selected from the ablest professional names; also orthopedic, ophthalmic, general and consulting surgeons, with proper representation upon the Medical Board.

"Resolved, That the President (Mr. Clark Bell) be instructed to appoint suitable persons for such medical services, and that in selecting the Medical Board, or committee, care be taken that the medical staff have proper representation thereon."

No reasons of any moment were offered in justification of the proposed change, and, although the medical members strongly opposed the action and referred to their records as conclusive evidence against the passage of the resolutions, they were, nevertheless, declared by the President to have been adopted. The majority necessary for the passage of these resolutions was obtained by the votes of gentlemen who had never before attended a meeting of the Board of Managers. All of the above measures were taken without any previous consultation with any of the physicians of the Board, and without any previous knowledge upon their part of any such action being intended.

In accordance with the provisions of these resolutions, the President offered various positions upon the medical staff of the Asylum to physicians of the city, who were, of course, ignorant of the circumstances surrounding the case. Some of the positions were accepted, others were declined; these latter have been tendered to physicians in turn, until, at length, the President seemed to regard his staff as complete, and issued a printed circular containing the names, etc., of the appointees. Some of the physicians whose names appear in the list had declined to accept the positions when offered them; and others, upon learning the facts as above set forth, resigned their places.

It would be absolutely false to assert that the needs of the Asylum had made necessary any radical change in its medical management.

Thus it is seen that the medical service of a worthy public charity

during many years has been satisfactorily administered by the physicians to whom it has been intrusted; and, also, it is apparent from the foregoing statements that this department has been, violently and without cause, wrested from the hands of those who have faithfully administered its affairs for the benefit of the patients, by persons who must have been from the nature of the case ignorant of the true requirements of the Asylum.

We lay these facts before the profession of the city, and ask whether such actions upon the part of a public charity toward its medical management should meet with the approval of the medical profession.

Yours, etc.,

JOEL FOSTER, M. D.,

Members of the Board of Managers of the New York Infant Asylum.

New Inventions, etc.

A TRANSFUSION APPARATUS.

BY HENRY J. GARRIGUES, M. D., NEW YORK.

The accompanying cut represents the apparatus which I used in the case of gas-poisoning reported in the issue of March 3d of this journal. It is essentially a diminutive Davidson's syringe. It consists of two rubber tubes united by a rubber bulb (B). A is a tin plunger.

At E and Ez are cup-shaped valves, allowing the fluid to go in the direction of the arrows, but not backward. C is a stop-cock, which is closed when the apparatus has been filled with blood, in order to prevent any escape of blood through the nozzle, and consequent entrance of air into the syringe. When the nozzle has been introduced into the vein, the stop-cock is again opened. D is a nickel-plated cannula, which can be taken off in order to make thorough cleansing easier. It is flexible, and ought to be bent a little, which facilitates the introduction and protects the tissues against pressure. *It is a fault in the figure that the curve goes in the opposite direction to the bend of the stop-cock; it ought to go in the same direction, as the stop-cock must, of course, point upward, and the posterior part of the cannula should be lifted up from the vein.*

The cannula is of very small caliber, in order that it may easily enter a collapsed vein. It is probe-pointed, in order to avoid puncturing the opposite wall of the vein. Finally, it is tapering, so as to fill up the small opening made in the vein, whereby loss of blood is avoided without the necessity of tying the vein, to the cannula.

This apparatus is destined for *indirect transfusion*, which presents great advantages over the direct transfusion from arm to arm. The blood-donor need not see the patient, nor even enter the sick-room, where he sometimes faints. The patient need not see the donor, which, in case he or she is conscious, may not be desirable. No needle is introduced into the donor's vein, which is a more serious interference than simply to puncture it, and let the blood flow out.

It is by far safer to use defibrinated blood than the blood in its natural condition, when even very small clots may prove a serious danger to the patient's life.

No other kind of blood than that from a human being ought to be

used, since experiments (Landois, Panum, Ponfick) have shown that heterogeneous blood-corpuscles not only are destroyed themselves, but cause the destruction of the patient's own blood-corpuscles, and give rise to infarctus of the kidneys.

Human blood is the best of all substances to inject, and, in case of poisoning, as ours was, it is particularly indicated as carrying into the poisoned blood red-blood corpuscles filled with oxygen by the beating of the blood. But sometimes it is impossible to obtain human blood, and experience has shown that different substances, such as milk, peptone, and saline solutions may with profit be injected into the veins of man to obviate acute anæmia. It seems that the effect in these cases is due to the mere increase of bulk of the fluid circulating in the heart and the blood-vessels.

When blood can not be obtained, I should prefer a saline solution, as containing no foreign substances and no solid corpuscles, being always obtainable, and not liable to be decomposed. Table-salt is found in every house, and all that is needed is to inject a solution of one half per cent. of this substance.

Miscellany.

M. GAMBETTA'S EYE.—So many stories have been told concerning M. Gambetta's eye, says the "Lancet," that it becomes necessary to re-establish the true facts of the case. The most popular account is that M. Gambetta, when quite a boy, destroyed his eye because his father refused to take him away from school; and this is related as a proof of his determined character. This version has, however, the disadvantage of being absolutely false. The injury was due to an accident. A tool escaped from the hands of a workman in a turner's shop, and struck Gambetta in the face, blinding him in one eye. Gambetta was but a boy then. In the course of years the anterior part of the globe gradually dilated and became so large that he could no longer close the eyelids. In 1867 Gambetta was introduced, by his friend Dr. Fienzal, to the celebrated oculist De Wecker, who declared that the wounded eye must be at once excised. De Wecker describes the operation, which he performed, in the "Gazette hebdom. de méd. et de chir." Gambetta, who was then living in a very modest apartment in the Rue Bonaparte, displayed great fortitude. Either was administered, and acted with exceptional rapidity; the operation was most successfully and promptly concluded. The eye, which was pear-shaped, had grown to double its normal size, and its antero-posterior diameter measured nearly five centimetres. In three days Gambetta was able to quit his bed, and he was very soon completely cured. De Wecker preserved the eye, but he ultimately lent it to the renowned histologist, Professor Iwanoff, remarking at the time that it was the eye of a man destined, he was sure, to enact an important part in the history of his country. Two years ago Professor Iwanoff died at Mentone, having still in his possession Gambetta's eye. This relic, together with Professor Iwanoff's collection, was handed over to his most devoted pupil, the Duke Charles of Bavaria, brother of the Empress of Austria and of the ex-Queen of Naples. Thus, the eye of the statesman and patriot who, as Dictator, contributed more than any one else to raise armies and resist the German invasion, is now in the hands of a German prince!

THE AYES AND NAYS ON THE NEW CODE.—A correspondent has furnished us with the following analysis of the recent vote on Dr. Squibb's resolutions to abolish the new code of the Medical Society of the State of New York, and assures us that it was made from an official copy of the vote furnished him by the Secretary, Dr. W. Manlius Smith. It will be seen that the new code had a majority not only of permanent members, but also of delegates.

In forty-one counties there were either permanent members or delegates who voted for the old code, while in twenty-eight counties there were those who voted for the new. The total number of counties in the State is sixty; of these, all but Cattaraugus, Delaware, Hamilton, Livingston, Richmond, Schoharie, Schuyler, Suffolk, Wayne, and Wyoming sent representatives who voted. The aggregate vote of

Kings County was twelve for the old code and five for the new; of New York, seven for the old code and thirty-seven for the new. In the two counties combined there were nineteen votes for the old code and forty-two for the new. Our correspondent remarks that these facts, shown by the subjoined list and table, effectually disprove some of the loose statements of one of our contemporaries as to how the new code is received by the profession throughout the State. It is seen that it has supporters in a large number of counties, and that Kings County and New York were by no means unanimous for its retention.

A DINNER TO DR. OLIVER WENDELL HOLMES.—At a recent meeting of medical men at the University Club, convened for quite a different purpose, it was resolved to tender to Dr. Oliver Wendell Holmes a complimentary dinner, as an expression of appreciation of the honor he has conferred on American medical and general literature during the past forty years. The time appointed for the dinner is the 12th of April. The following gentlemen constitute a general Committee of Arrangements: Dr. Furdycce Barker, Honorary Chairman; Dr. T. Gailard Thomas, Chairman; Dr. Paul F. Mundé, Treasurer; Dr. George L. Peabody, Secretary; Dr. A. Brayton Ball, Dr. William T. Bull, Dr. John G. Curtis, Dr. Benjamin F. Dawson, Dr. William H. Draper, Dr. Frank P. Foster, Dr. Allan McLane Hamilton, Dr. Everett Herrick, Dr.

Frank P. Kinnicutt, Dr. E. G. Loring, Dr. Charles McBurney, Dr. Charles I. Pardee, Dr. Henry G. Piffard, Dr. William M. Polk, Dr. Beverley Robinson, Dr. D. B. St. John Roosa, Dr. Charles D. Scudder, Dr. A. A. Smith, Dr. A. H. Smith, Dr. Lewis A. Stimson, Dr. Frederic R. Sturgis, Dr. Charles S. Ward, Dr. Robert F. Weir, Dr. George G. Wheelock, Dr. Leroy M. Yale, Dr. John C. Dalton, Dr. Francis Delafield, Dr. Alfred L. Loomis, Dr. David Webster, Dr. Edward L. Keyes, Dr. Francis M. Weld, Dr. J. H. Anderson, Dr. George M. Lefferts.

It is announced that tickets will not be sold after April 1st, and, as the capacity of the hall is limited, we are asked by the committee to say that those desiring tickets should apply for them before that date. They are to be had, at ten dollars each, of Dr. E. G. Loring, 128 Madison Avenue; Dr. F. R. Sturgis, 16 West Thirty-second Street; Dr. J. G. Curtis, 127 East Thirtieth Street; Dr. G. G. Wheelock, 75 Park Avenue; or Dr. P. F. Mundé, 20 West Forty-fifth Street.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—The twenty-second annual commencement exercises of this institution were held at Chickering Hall on Wednesday evening, the 14th inst. After a prayer by the Rev. Samuel D. Burchard, D. D., the degree of doctor in medicine was conferred on one hundred and sixty-seven gentlemen by the President of the Faculty, Professor Isaac E. Taylor. An address to the graduates was then given by Professor Samuel D. Gross, of Philadelphia, and the valedictory was delivered by E. A. Morgan, M. D., of the graduating class.

THE MEDICAL DEPARTMENT OF THE ARKANSAS INDUSTRIAL UNIVERSITY.—We are indebted to a correspondent for a copy of the "Daily Arkansas Gazette" of the 1st inst., in which we find an account of the commencement exercises of the Medical Department of the Arkansas Industrial University. The graduating class numbered only four—W. H. Moore, of Washington County, T. R. Rutherford, of Clark County, B. S. Zachery, of Pope County, and J. P. Basham, of Johnson. All of these gentlemen took prizes, one of them securing four in addition to an "honorable mention."

DEATH OF DR. F. D. BAGLEY.—Dr. Fillmore D. Bagley died of acute articular rheumatism on Saturday, the 10th inst., at his residence, in East Broadway, at the age of thirty-three. Dr. Bagley was a graduate of the Medical Department of the University of the City of New York, in the class of 1878, and was a clinical assistant in that institution at the time of his death. He was also connected with the Eastern Dispensary. It has been announced that his remains were to be taken to his native town, Troy, Me.

NAVY INTELLIGENCE.—According to the "Army and Navy Journal," the court-martial in the case of Passed Assistant Surgeon W. G. G. Willson, recently tried at Norfolk, found him guilty in a less degree than charged, and sentenced him to thirty days' confinement to the limits of the Swatara. The sentence was approved by the Secretary of the Navy; but, as the Swatara had sailed, the punishment was remitted, and Dr. Willson was released. —Surgeon J. W. Coles has been detached from the Nipsic, and placed on waiting orders. —The appropriation for the year ending June 30, 1884, includes \$130,000 for the Bureau of Medicine and Surgery.

ARMY INTELLIGENCE.—Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 3, 1883, to March 10, 1883.—BROWN, HARVEY E., Major and Surgeon. To be temporarily assigned to duty at Mount Vernon Barracks, Alabama, during the absence on leave of Captain T. A. Cuningham, Assistant Surgeon. Par. 2, S. O. 17, Department of the South, March 6, 1883. —CALDWELL, D. G., Captain and Assistant Surgeon. To be relieved from duty at Fort Fred. Steele, Wyoming, and will report in person to the commanding officer at Fort Laramie, Wyoming, for assignment to duty at that post. S. O. 23, Department of the Platte, February 27, 1883. —HOPKINS, WILLIAM E., First Lieutenant and Assistant Surgeon. The leave of absence granted December 28, 1882, is extended two months. Par. 5, S. O. 56, A. G. O., March 9, 1883. —PAULDING, H. O., Captain and Assistant Surgeon. The leave of absence granted in S. O. 11, Department of the Platte, January 27, 1883, is extended twenty days. S. O. 23, Military Division of the Missouri, March 2, 1883.

Lectures and Addresses.

LECTURES ON
HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., Etc.

LECTURE III.

Secondary or Acquired Automatism of the Human Body. Habitual Movements, as those of Walking, Balancing, Music Playing; their Continued Performance in Profound Sleep, and even in Coma. Morbid Activities of the Same Class.

THE subject of the "secondary" or "acquired" automatism of the human body, to which I have to ask your attention this evening, is one of very considerable interest in itself; and I would the more press it on your attention because I think that the study of it gives us the key to the mental automatism which will furnish the subjects of the latter part of the course. The conclusions to which pure metaphysicians have come as to the nature of these movements will not for a moment stand the test of scientific scrutiny. The manner in which they have treated the subject, indeed, shows the absolute necessity of bringing a thorough knowledge of physiology into any investigation which relates either to the physical or the mental life of man. If, for example, you will look into the writings of Dugald Stewart, one of the ablest of the Scotch metaphysicians, you will find that he maintains the act of walking or riding to be always necessarily *voluntary*, because it was originally voluntary. And he represents the will as in a state of oscillation between the train of ideas whose coherence is maintained by it while we are thinking out a subject by ourselves or conversing with a friend and our simultaneous locomotive action, which (he thinks) must also be maintained by volitional impulses alternating with those which direct our thought. Again, it has been taught by others that an infinitesimally small quantity of will is necessary to keep up these movements when they have become habitual; which seems to me really equivalent to saying that no will at all is needed—and this is what I think I shall be able to show you is the real fact.

You have seen that in the lower tribes of animals the ordinary movements of locomotion are provided for in the mechanism of the animal itself; and the working of that mechanism does not require anything more than guiding sensations. (You will remember how I demonstrated this to you in regard to the centipede.) I shall now go over the same ground in regard to the frog, in which animal we shall find that actions even much higher than those of the centipede may be performed after the removal of the cerebrum, nothing else being left than that "axial cord" * which I re-

gard as furnishing the nerve-center of the whole of the mechanism of automatic movements, whether original or acquired.

In the frog this mechanism is probably original—a part of its hereditary constitution. We shall not go into the question of evolution, and consider how this creature has come to be what he is, but will merely take the frog as we find him, and see what he will do.

You are all familiar with the general attitude and position of the frog, and know that the hind legs constitute his principal instruments of locomotion. Now, suppose that frog's head to be cut off and the body to be placed upon the table in its usual attitude; if, then, you pinch one of its feet, the frog will jump. Further, if a little acid be applied to the central part of the thigh, the other foot will make a movement (I was going to say "will try") to wipe it off. We can not say that the frog tries to do this, because it is done by the headless trunk. Nay, more: if that foot be cut off, the other foot will make a movement to do it. Then, again, if the cerebrum of the frog be taken out, leaving intact the spinal cord with the ganglionic centers of the nerves of sense within the head (this "axial cord" representing the entire nervous system of the centipede), the frog remains in a very curious condition. It is as if asleep, and yet not asleep; for it can be very easily excited to move, but will remain stationary unless excited. If its foot be pinched, it will jump; and the direction of this jump will show it to be influenced by the presence of any obstacle placed before its eyes. Remember that the optic ganglia still remain untouched and uninjured, so that the frog, we have reason to believe, can *see*, although (its cerebrum having been removed) it would probably not be able to form—if it forms at any time—distinct conceptions of what it sees. The impression made by sight of the obstacle directs its leap so as to avoid it, just as it directs the movements of the centipede, or those of a man walking in a state of profound abstraction. Again, on stroking a particular part of the skin of the frog, its characteristic croak may be called forth. One of the most curious phenomena of this state is, that if the frog be placed on the hand, and the hand be then inclined so that the frog would fall off if he did not take some measures to avoid it, the fore feet will advance over the top of the hand so as to hold on; and by moving the hand slowly round, the frog may be made to pass from one side of the hand to the other, creeping over the top edge as the other side becomes the uppermost.

Remarkable as these facts are, I do not see in them any indication of conscious or purposive voluntary action; because I shall be able to show you that we ourselves go through a similar performance, executing a course of action of the same kind, in a state which is parallel to that of the frog, when our cerebral activity is either entirely suspended or is being

* This term I have been long in the habit of using to designate the spinal cord with the sensori-motor ganglia anterior to it, which constitutes (in my view) the true center of all nerve-action, the cerebrum being a superadded organ that is not merely acted on through the axial cord alone, but also reacts only through it. This has always seemed to me the obvious teaching as well of comparative anatomy as of the

history of development, and it is with some satisfaction, therefore, that I recognize, in the modern results alike of anatomical, of experimental, and of pathological inquiries, a constant convergence to this conclusion. See especially the treatise of Dr. Lusa on "The Brain and its Functions," constituting vol. xxxviii of Appleton's "International Scientific Series."

directed into another and altogether different channel. I believe, therefore, that all the actions of the frog which are immediately concerned in the maintenance of its animal life are provided for in its original mechanism, whereas in ourselves the mechanism for their performance has to be constructed in the course of the growth and development of each individual. This mechanism has for its center (in my view) not the cerebrum, but the axial cord on which the cerebrum is superposed. It is in the series of sensori-motor centers which lies along the floor of the brain-cavity, and which communicates by the radiating fibers that constitute the "white" or "medullary" substance of the cerebrum, with the "gray" or "cortical" substance that forms its convoluted surface-layer and constitutes it a ganglionic center, that all the sensory nerve-trunks seem to terminate, and that all the motor nerve-trunks seem to originate; so that it is (to say the least) very doubtful whether the nerve-fibers of either class have any other connection with the ganglionic substance of the cerebrum than that which is made for them by the intermediation of the sensory and motor tracts of the axial cord. Everything, in fact, seems to me to indicate that the higher work of the cerebrum is done upon the information (so to speak) which it receives through the sensory ganglionic tract of this cord; and that, when this work expresses itself in movement, the cerebrum does not operate directly upon the muscles to be called into action, but gives its orders (as it were) to the motor ganglionic tract of the cord, by which they are carried into execution. Every pathologist knows that in almost all cases of paralysis, whether sensory or motor, or both, it is in the ganglionic tract at the base of the brain that we find the injury; not in the cerebrum proper; and that even great injuries to the cerebrum do not at all necessarily, or even generally, produce paralysis; the essential part of the motor apparatus often remaining intact, although the organ by which it is worked may be partially thrown out of gear. This is well seen in cases of the affection termed *aphasia*, in which the defect of cerebral action resulting from local malnutrition manifests itself in the loss of memory of words—the mechanism of speech remaining wholly unaffected. And, even when, through interruption of the communication between the cerebrum and the upper part of the axial cord, there is complete paralysis as regards voluntary movement, the involuntary movements of "expression," as well as purely reflex movements, are often performed by the muscles which the strongest effort of will is powerless to call into action.

I was prevented, by want of time, from mentioning in my last lecture that we have distinct proof of the independent action of parts of this axial cord in the fact that injury often separates its lower part from its upper part, and that the lower part still retains enough reflex power to produce movements when certain stimuli are applied. Cases occur in hospital practice from time to time (the first were recorded by my late valued friend, Dr. William Budd, of Bristol, some forty or forty-five years ago) in which there is an accidental injury of the spinal cord in the lower part of the back; a man, for instance, falling down from the mast of a ship, across some projecting object, by which his spine is seriously injured. The lumbar portion of the spinal cord, which is the

immediate center of the nerves of the legs, may not suffer from anything but a temporary concussion; but it is cut off from communication with the cerebrum through the upper portion. What, then, is the consequence? The man is perfectly paralyzed as regards the voluntary actions of his legs, neither does he *feel* any impression made on them by pricking, pinching, burning, tickling, or any other irritation; and yet if the soles of his feet be tickled, or a warm plate be applied to them, the feet are immediately drawn away by the muscles of the legs. Such cases afford our best proof that these reflex actions are not in the least degree dependent upon consciousness, although attended by consciousness in our ordinary perfect condition, since they are performed in exactly the same way when the patient is prevented from *seeing* the application of the stimulus, of which he is kept altogether unaware. Now, I can not doubt that what is true of man is true also of the frog; and that we may recognize in the corresponding actions of the frog the same fundamental condition—namely, that they can be performed without consciousness.

Now, what is the fact with regard to ourselves? Take the act of walking. We shall presently consider what is involved in that act; I merely speak of it now as one of those well-known secondarily automatic combinations of muscular movement which we learn in infancy, and which abide with us (as it were) through the whole of our active lives. It is perfectly well known that men may walk in a state of complete unconsciousness; for this happens not only in the state called "sleep-walking," in which there is consciousness, though often so limited as to be entirely wanting in relation to bodily movement, but in profound sleep. Officers in the army have seen almost whole regiments so marching in this condition at the end of a long and fatiguing day. It is equally well known in regard to riding; men having come in from a long ride, sitting on their horses and balancing themselves, though in a state of sleep so profound that it was necessary to wake them before getting them to dismount, the horses having found their way home by themselves.

These very simple and well-known facts at once (I think) disprove the idea that the actions of walking and riding are necessarily dependent on the will when once they have been established as regular consentaneous parts of our motor activity.

Now, observe what is involved in this act of walking; not only the onward propulsion by the alternate movement of the legs, but a fresh balancing of the body at every step, in which almost every muscle is called into activity. You know, I dare say, what Paley has said of the young child learning to walk—that he is the greatest posture master in the world; and I do not think this at all untrue. Look at a young child first put upon his legs and encouraged by his father or mother to run across the room alone; you can see at once that the little one is giving the whole energy of his small nature to the combination required in the exercise of his muscles, so as to maintain his equilibrium while putting one foot before the other. It is well known that though many mechanicians have applied themselves to the production of walking automata, no one has ever succeeded, for the complexity of the mechanism required is such that it

seems even beyond the capacity of the most ingenious inventor to devise it.

The balancing of the body as well in the lateral as in the back and front direction, which requires the transfer of the center of gravity—not only from one side to the other, but also from behind forward—so as to keep it always over the base of support, which is being constantly shifted, not only by our change from one foot to the other, but by the onward movement of each foot alternately, requires altogether such a complexity of adjustments as is probably unparalleled elsewhere; and yet how perfectly simple and easy do we find it to make them when we have once acquired the habit of doing so. Take, again, the balancing, not so much of an ordinary rope-dancer aided by his weighted pole, as of such a wonderful performer as Blondin. You all doubtless remember that he could walk (without any such aid) upon a rope stretched across the great chasm of Niagara, and even wheel a barrow before him containing a living man, and yet feel himself as perfectly secure upon that rope as you or I would feel in walking across a bridge two feet wide of whose security we were assured, though without a rope or railing on either side. I suppose that none of us would have any difficulty in doing this if such a bridge spanned a shallow stream immediately beneath. And it is only either physical giddiness, or the emotional disturbance produced by the sight of the yawning chasm and the roaring torrent beneath, that would interfere with our doing this equally well at a height of two hundred feet above Niagara, such disturbance interfering with the due action of the automatic mechanism. Of those who are subject to it I am not speaking; but of those cool-headed persons who, when well assured of the security of their footing, can feel that they have nothing to do but to walk straight on, just as if the two-foot plank were level with the floor. Now, just as any person possessing the requisite self-reliance and self-control could easily train himself to cross even the chasm of Niagara on a plank broad enough to allow him to walk in his ordinary mode, and might even do it more easily if thinking of something else all the time, thus keeping himself free from perturbing influences—so (I have very little doubt) could Blondin walk across on his rope while his mind was otherwise continuously engaged, in virtue of the consummate perfection to which he had brought the balancing action of his automatic mechanism. Now, in all such conditions, I hold that the cerebrum is as completely dissociated from the action as if it had been taken away altogether, the axial cord furnishing its whole mechanism.

I will give you another illustration of my meaning. Any of you who look into a very interesting and suggestive book, the autobiography of Robert Houdin, the French conjurer, will find in it how he trained himself to the power of juggling with balls—keeping the balls up in the air by what is commonly called "sleight of hand," simply manual dexterity—at the same time that he could continuously fix his attention upon a book before him. He did this with a purpose. In his early years he foresaw that in educating himself for the course of life he was intending to follow it was necessary that he should be able to carry on these manual operations while his mind was intent upon something else; and he prac-

ticed this until (he said) he was able to keep *four* balls in the air at once without any withdrawal of his attention from the book he was reading. Now, while he is writing his memoirs, he says: "The thought comes over me that I should like to try whether I can do this *now*; it is thirty years since I did it, but I will make the attempt." He comes back to his writing, and says: "I found I could keep up *three* balls, and still read my book." Now, that shows, I think, how the mechanism was created by a continuous determinate training, in the first place, entirely kept up by an effort of the will; but it also shows how that volitional training had so impressed itself upon the organism—had so determined, in Houdin's earlier years, the growth and development of that part of his nervous system—that it shaped itself according to the mode in which it was habitually exercised, and thus became able to act of itself and by itself, simply being set going by the action of the will. And that seems to me to be the very simple physiological explanation of the fact, which was first given by a very able thinker, who was at the same time a metaphysician and a physiologist, David Hartley, a writer with whom many of you are doubtless familiar. His great work "On Man" (1748) may be read and studied with advantage even at the present time; for we have only to translate his "vibrations" into "nerve-currents" to make his physiology accord with modern views; and his development of the doctrine of association is a masterpiece of philosophic thought. There is scarcely any point in which I am not in fundamental accordance with him, except that he does not recognize the directing and controlling power of the will, his system being one of automatism, pure and simple.

I am so desirous to make this doctrine clear to you that I shall give you some further illustrations of the manner in which, when these habitual tracks (so to speak) have been once laid down, the mechanism works of itself, under conditions in which the will must be entirely in abeyance. And I shall first speak of actions performed in states of perfect insensibility. A man was brought, a few years ago, into one of the London hospitals in a state of profound coma, the result of the rupture of a blood-vessel in the brain, and died in a few hours, without showing any sign whatever of consciousness. He was a very finely developed man, and had a very handsome pair of mustaches. Through the whole of this state of profound insensibility he was continually putting up first one hand and then the other to give his mustache a twirl; and it was found, on inquiry made after his death, that, having been formerly a soldier in the Guards, and afterward a policeman, he was always exceedingly proud of this pair of mustaches, and that during life he would seldom pass many minutes without putting up his hand and giving them a twist to keep them in a proper curl. I remember reading in my boyhood an observation made by a very accomplished physician of Manchester, Dr. Percival, who narrated that, having once been called to an old lady in a fit of apoplexy, among various attempts that were made to arouse her consciousness, a feather was introduced into her nostrils, upon which he noticed that, whenever this feather was pushed up far enough, the forefinger and thumb of her right hand closed together. This old lady had been an habitual and inveterate snuff-taker.

I have two cases of the same kind from the records of French hospitals, and they are both of them rather curious. Of one man in this condition it is stated that, when a piece of cord was put into his hand, he would immediately begin to turn and twist it; this man had been a rope-maker. Of another, an old woman completely paralyzed as to her lower extremities, blind, and lying for some time (as was believed) in a state of complete unconsciousness, we are told that if the end of a bandage or a partly rolled piece of linen were put into her hand, she would immediately begin to roll it up. That woman had been early a patient in another hospital, and had been there kept during her whole life in the linen-room, where her employment was especially to roll bandages.

(To be concluded.)

MEDICAL ETHICS AND ETIQUETTE.

COMMENTARIES ON THE NATIONAL CODE OF ETHICS.

By AUSTIN FLINT, M. D.

Second Article.

THE DUTIES OF PHYSICIANS TO THEIR PATIENTS, AND THE OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS.

ART. I.—*Duties of Physicians to their Patients.*

SECTION 1. A physician should not only be ever ready to obey the calls of the sick, but his mind ought also to be imbued with the greatness of his mission, and the responsibility he habitually incurs in its discharge. These obligations are the more deep and enduring, because there is no tribunal other than his own conscience to adjudge penalties for carelessness or neglect. Physicians should, therefore, minister to the sick with due impressions of the importance of their office, reflecting that the ease, the health, and the lives of those committed to their charge depend on their skill, attention, and fidelity. They should study, also, in their deportment, so to unite *tenderness* with *firmness*, and *condescension* with *authority*, as to inspire the minds of their patients with gratitude, respect, and confidence.

The sentiments so admirably expressed in the foregoing first paragraph of the code need no arguments for their support, nor any comments to increase their force. They antagonize undue influences arising from self-conceit, an irritable temper, indolence, devotion to pleasure or to occupations which divert from professional duties, and all mercenary considerations. At the same time, they do not contravene self-respect and a proper regard for personal interests. It is not to be assumed that the practice of medicine is a sacred calling in the sense in which this expression is applied to the clerical profession, nor that it is adopted for purely benevolent or philanthropic purposes. The medical profession holds out to its candidates the inducements of an honorable pursuit, studies which are not only attractive, but afford ample scope for the mental faculties, labors which may carry with them the satisfaction of saving life and restoring health, but, conjoined with these, an expectation of gaining a livelihood, together with means for the enjoy-

ment of the pleasures of domestic and social life, a fair prospect for acquiring a competency, and, with prudence and perseverance, even wealth. The last of these inducements are by no means necessarily inconsistent with the higher sentiments which should govern the conduct of physicians. Self-abnegation is a noble trait, not infrequently exemplified in the lives of members of the medical profession, but communities have no more right to demand it of them than of those in other callings, and indifference to their own worldly interests and the claims of their families is not to be enjoined upon them more than upon those engaged in other pursuits. This principle is one to be understood both by physicians and the public. Writers of fiction and dramatists have depicted lives devoted to the duties of medical practice purely as works of charity.* These delineations have their analogues in real life. On the other hand, there are those whose absorbing aim is to acquire either distinction or pecuniary gain. Without undertaking to interfere with motives and objects, for which every one must be responsible to his own conscience, the code of ethics places before the mind of the physician sentiments peculiarly applicable to the exercise of the medical profession.

Sec. 2. Every case committed to the charge of a physician should be treated with attention, steadiness, and humanity. Reasonable indulgence should be granted to the mental imbecility and caprices of the sick. Secrecy and delicacy, when required by peculiar circumstances, should be strictly observed; and the familiar and confidential intercourse to which physicians are admitted in their professional visits should be used with discretion, and with the most scrupulous regard to fidelity and honor. The obligation of secrecy extends beyond the period of professional services; none of the privacies of personal and domestic life, no infirmity of disposition or flaw of character observed during professional attendance, should ever be divulged by the physician except when he is imperatively required to do so. The force and necessity of this obligation are indeed so great that professional men have, under certain circumstances, been protected in their observance of secrecy by courts of justice.

Most persons, of "all sorts and conditions," regard physicians with respect in consideration of their calling. Even they who are notoriously rough and uncivil in their intercourse with others are often gentle and courteous to those from whom they expect to receive medical aid in sickness. As a rule, the physician, in his visits to his sick patients, receives kindness and confidence. It may, however, be otherwise as a consequence of the influence of disease upon the mind. Disease not infrequently renders persons impatient, querulous, irritable, distrustful, suspicious, and these morbid mental conditions may manifest themselves in language and manner, perhaps, much at variance from the traits of character belonging to the same persons when well. Both propriety and policy dictate the utmost forbearance under these circumstances, on the ground that one is not to be held responsible in sickness for utterances and conduct which in health might properly involve accountability. The physician does not compromise his self-respect by submitting patiently to rudeness, or even insults, from a sick patient, to

* E. g., "Le médecin de campagne," by Balzac.

which he would be by no means bound to submit quietly if the patient were well. This ethical rule is not, at least to the same extent, applicable to the friends of patients. But here allowance is often to be made for the disturbance of mind arising from anxiety and apprehensions. Less allowance is due to officious visitors and acquaintances. Forbearance toward these is not always to be embraced within the scope of medical ethics. Prudence and tact are to be exercised according to the circumstances in particular instances.

On the part of the physician, it is a gross impropriety to require the forbearance of his sick patients and their friends. For him there is not the excuse which the latter may fairly claim. Roughness and the lack of courtesy on his part are the more inexcusable for the reason that patients and their friends are, in a measure, at his mercy. They have a right to expect from him kindness and patience, and, if he be lacking therein, he is not entitled to the indulgence which is due to them, if they be deficient in these regards. Brutality toward patients or their friends is a grievous offense against the medical profession. It is especially reprehensible toward hospital patients, or those from whom no pecuniary recompense is expected. Private patients in good circumstances can elect and change physicians. This is a privilege denied to those who seek relief in public institutions, or to whom medical services are gratuitously rendered; hence, it is taking a mean advantage not to treat such patients with attention and humanity.

The binding force of secrecy as regards all information obtained in connection with professional relations, whenever it is desired, or is desirable, on the part of patients or their friends, that the information should not be communicated to others, is not sufficiently appreciated by many members of the medical profession, and still less is it appreciated by the public. Weaknesses, foibles, and vices, perhaps unsuspected by others, become known to the physician. He can not help knowing them if he would. No one but himself is to be the wiser for this knowledge. Physical ailments and defects which the physician must discover, he has no right to speak of. Confidential communications by patients relating to themselves, their families, or their progenitors, are to be held as a sacred trust.

Physicians should be reserved, and exercise judgment in speaking of the ailments of those under their care. Many ailments are of a nature that most persons desire to conceal, and they should not be deprived of the right of concealment. It can not, for example, be agreeable to a young woman for her acquaintances to know that she is troubled with a tapeworm. Other affections of a much more delicate nature might be cited as examples. The right of concealment by no means belongs exclusively to the female sex. Moreover, a patient may have a serious disease, of which, in order to spare family and friends anxiety, or for other reasons, concealment is desired. The physician is bound to respect this desire. A physician who appreciates fully the duty of secrecy can not but feel that it is a reflection upon his professional character when, as often happens, he is requested by a patient to observe this duty. It is true that some patients are not sensitive on this sub-

ject, and they may even desire that others may know of the nature of their maladies. Under these circumstances the physician is, of course, absolved from the duty of secrecy. He is not, however, to act upon his own presumption in the matter, when the feelings of his patients can be readily ascertained.

A more judicious reserve than is now practiced by not a few physicians would soon lead to a better understanding of the ethical duty of secrecy on the part of the public. How common is it for a practitioner to be asked, "What is the matter with Mr. —, or Mrs. —, or Miss —?" The answer is expected to embrace the nature and seat of the disease, the symptoms which are present, and, perhaps, all the details of the sick-room. If a patient happen to be a person of note, the attending physician is liable to be called upon by an interviewer, who expects to get the diagnosis, the symptomatic history, the prognosis, and the treatment, for publication in a newspaper. Now, the ground is by no means to be taken that nothing is to be communicated to friends, acquaintances, or the public respecting cases of disease. It would be simply absurd to take this ground. The condition of a patient in respect of danger, and, in some instances, the probable duration of disease, may properly be made known to those who are interested in the patient's welfare. It is sometimes proper and sometimes not to state the nature of the disease. It may not be proper to go further. Of this, the physician must be the judge. It should be left to his judgment and sense of propriety or duty how much should be told of details belonging to the privacy of the sick-room. Intelligent, well-bred persons, who have reflected upon the duty of a physician in respect of secrecy, will never place him in the unpleasant position of declining to answer questions relating to his patients.

Physicians have to deal with malingering. When called upon to decide whether or not persons are malingerers in prisons, in the army and navy, in hospitals, and other public institutions, and when impostors undertake to deceive the public by feigning diseases, either for gain, sympathy, or notoriety, there can be no question as to the duty of exposure. In private practice the duty will vary according to the circumstances in individual instances. The duty then points to the course which will be most productive of good, and with regard to this the physician is to exercise his judgment. In an instance like the following it seems plain that secrecy would have been improper: A young man, the son of a wealthy father, feigned paroxysms of intense pain and convulsions, and at times unconsciousness. He had imposed upon a medical adviser so far as to obtain from the latter a written statement that he would probably never recover, and was liable to die in one of the paroxysms. When he had reason to know that his deception was discovered by another physician, he became abusive in the extreme, instead of asking for concealment, with a promise that the malingering should cease. Under these circumstances the diagnosis was stated to the parents, and the case relinquished. Secrecy outside of the family in such an instance would be proper, provided the diagnosis was not kept by them a secret, and the physician was not called upon to

defend its correctness. There are instances, however, the object being to awaken interest or affection, in which exposure is not the physician's duty, inasmuch as it will not do good and may do much harm. It may be a question whether the physician should ever dissimulate so as to appear to be himself deceived. Policy may seem to dictate this course. As a rule, it is more consistent with professional character to undeceive the malingerer at a proper time and in a proper way; otherwise, the physician becomes an accomplice in the fraud. With regard to secrecy beyond this, there can be no better rule than to pursue the course which will do the least harm or the most good to all concerned.

In respect of the knowledge of criminal acts, the physician is not to play the part of a detective or an informer. Some may consider it a strong assertion that a physician is under an ethical bond of secrecy when, through his professional intercourse, he may have ascertained that his patient is an escaped convict, a thief, a robber, a forger, or even a murderer. No matter how heinous the crime, the wretched criminal has a right to medical services in sickness. Who can tell how important it may be that his health should be restored and his life prolonged by these services, albeit in the light of human judgment it might seem better that he remain prostrated by disease or die. The duty of the physician in such instances relates exclusively to the patient. He would be debarred from medical services were it understood that physicians are to play the part of detectives and informers. It may be said that a distinction should be made as to the nature and degree of crimes which patients have committed. But where is the line to be drawn? It is not for the physician to exercise a judicial discretion on that point. The ethical rule is without exceptions. Medical men do not always appreciate the binding force of this rule, and disastrous effects sometimes follow its non-observance. The following recital is in illustration:

An unfortunate young woman had sought to escape the disgrace of maternity, and is a victim of malpractice. A physician is called to attend her in her extremity. He recognizes the nature of the case and the dangerous condition of the patient. He demands, in the cause of justice, to know the name of the author of her trouble, and of the one who had undertaken a criminal interference. An officer of justice is summoned to receive her testimony. The woman dies. The newspapers give publicity to the case, with all its details. The physician acted from his sense of duty, his object being the punishment of the offenders against the law. As results of his action, the moral effect of the steps taken in behalf of justice may have contributed to the death of the patient, and, at least, it is fair to conclude that the misery of her last hours was thereby increased; she left a dishonored memory; disgrace was brought upon the relatives of both parties, he being a husband and the father of a family. After all, the surviving offenders eluded punishment. This is not a hypothetical case. It is left to the reflections of the reader, with but brief comment. In no point of view was the action of the physician to be justified, although taken with good intentions. Knowledge of the fact of malpractice was essential to a proper appreciation

of the case. Further knowledge was not essential, and it was taking an ungenerous and improper advantage to demand it. Compliance with the wishes of the patient, voluntarily and deliberately expressed, could afford the only ground for excuse in the non-observance of secrecy.

The duty of the physician in giving testimony as a medical witness may be regarded from two points of view, namely: medical ethics, and existing laws relating to the subject. As regards the former, he must be himself the judge; in the latter, he will be instructed by legal advisers and the courts. It may happen that there is not agreement in these two points of view; in other words, he may be required to give testimony respecting matters which, in his judgment, are in the category of professional secrets. He must decide in such a case whether he will act in opposition to his convictions of ethical duty, or refuse to testify and accept the consequences, whatever they may be. One who has confidence in his own interpretation of duty, and holds the dictates of conscience to be above all other considerations, will refuse to testify, provided he have firmness enough to take that position. On the other hand, a refusal will not come from those who are distrustful of their ability to judge correctly of ethical duty, or from those who believe that in a conflict between the dictates of conscience and the interpretation of existing laws the latter should prevail; or, again, from those who would rather yield than submit to the consequences of not yielding.

The section of the code of ethics prefixed to these remarks is definite and comprehensive as to the duty and the scope of professional secrecy. Aside from the sense of honor and humanity, this portion of the code affects practitioners of medicine merely in relation to policy. The interests of the public, much more than those of physicians, are involved in this portion of the code. But, in view of these interests, it should be an object with members of the medical profession to secure the enactment of laws which are in full agreement with the letter and the spirit of the code. Testimony which involves a violation of medical ethics should not only be not required, but prohibited. For declining to give testimony, a declaration under oath that it would be a dereliction of the duty of secrecy should suffice.

In the laws of the State of New York there is a statute which is in harmony with the code of medical ethics. It is headed "Physicians not to disclose Professional Information," and reads as follows: "A person duly authorized to practice physic or surgery shall not be allowed to disclose any information which he acquired in attending a patient in a professional capacity, and which was necessary for him to act in that capacity."

A summary of the New York cases, and examples drawn therefrom, may be of interest to the reader.*

"It must be assumed, from the relationship existing, that the information would not have been imparted except for the purpose of aiding the physician in prescribing for the patient. Information means not only communications received from the lips of the patient, but such knowledge as

* Furnished by a legal friend, Edward H. Strobel, Esq.

may be acquired from the patient himself, from the statements of others who surround him, or from observations of his appearance and symptoms." *Edington vs. Mutual Life Insurance Company*, 5 Hun., 1.

"But communications made to persons in attendance at the office of a physician during his absence, and not shown to have been made as the basis of a prescription, are not privileged." *Gray*, 2 Hill, 300.

"Nor does the statute preclude the physician from testifying to the nature of the disease and the character of the treatment when he sues to recover for his services." *Kendall and Gray*, 2 Hill, 300.

"But whenever a visit is regarded and acted upon as professional, the statute applies; as, for example, when a wounded man accused of murder was visited by two physicians at the request of the coroner, held on the trial that the physicians could not as witnesses disclose the information that they acquired on such visits, as the prisoner knew them to be physicians, and submitted to questions for that reason." *People vs. Stout*, 3 Park. Cr., 670.

"In an action for divorce, the physician can not be required to testify to conversations which were held with him in his professional capacity, although these conversations tended to establish adultery." *Hume vs. Hume*, 1 N. Y. Sup., 499.

"Nor can a physician be required to testify whether a person had venereal disease when under his care." *Sloan vs. N. Y. C. R. R.*, 45 N. Y., 125.

"There seem to be the two following exceptions to the statute: An application to a physician for means of procuring an abortion, accompanied by a disclosure of the female's name, is not privileged, the ground of the decision being that it was doubtful whether such a communication should be considered as made while consulting the physician professionally, and that the information was not essential to enable him to prescribe." *Hewitt vs. Prince*, 21 Wend., 79.

"The statute creates merely a privilege in favor of the patient, and there is no person, after the patient's death, entitled to assert it. Hence, the statute has no application when a physician is called, in probate of a will, to testify touching the capacity of the deceased patient." *Allen vs. Public Administrator*, 1 Bradf., 21; Wend., 79.

"Both these exceptions are doubted in *Edington vs. Life Insurance Company*, on appeal to Court of Appeals, 67 N. Y., 185. The latter exception was virtually overruled in that case, it being held that the protection which the law gives to professional confidence does not cease upon the death of the party; the seal which the law fixes upon such communications remains unless removed by the party himself or his legal representative."

"It must be understood that the privilege is that of the party and not of the witness. The testimony of a physician, if not objected to by the patient, is admissible. If the party interested waive his right, the physician may be examined." *Johnson vs. Johnson*, 14 Wend., 637.

A statutory law substantially the same as in the State of New York exists in the following States of the Union: Missouri, Wisconsin, Iowa, Indiana, Michigan, Arkansas, and California.

The law in England makes the divulging of professional secrets compulsory. "In the case of the Duchess of Kingston, it was decided that in a court of justice medical men are bound to disclose these secrets when required to do so. Lord Mansfield said on that occasion, 'If a medical man voluntarily revealed these secrets, to be sure he would be guilty of a breach of honor and of great indiscretion, but to give that information which by the law of the land he is bound to do will never be imputed to him as any indiscretion whatever.' In that case Sir C. Hawkins, who had attended the Duchess as a medical man, was compelled to disclose what had been communicated to him in confidence. This is the leading case in England, and fixes the law in that country; or, in better words, it is the common law rule." It will be noted that the decision referred to takes cognizance only of the rights of the medical man, not those of his patients.

The law in France recognizes fully the obligation for secrecy on the part of physicians, as appears from the following citation: "*Obligation des médecins envers les particuliers qu'ils traitent.*"

"Comme un médecin est souvent dans l'occasion de connaître les secrets de ses malades, soit par la confiance qu'on peut avoir en lui, soit par les conjonctures qui rendent sa présence nécessaire, lorsqu'il est question de quelque affaire secrète, il est de son devoir de ne point abuser de ce qui est venu à sa connaissance, et de garder à cet égard un secret inviolable. Ce secret est ordonné par un article des statuts de la faculté de médecine, qui porte: *Aegrorum arcana, visa, audita, intellecta, nemo eliminat.*" —Merlin, "Repertoire de jurisprudence," tome 20, titre, "Médecin," § 111.

TRICHINIASIS IN ITS RELATION TO PUBLIC HEALTH AND NATIONAL ECONOMY.

By FRANK S. BILLINGS, VET. SURG.,

BOSTON.

Second Article.

(Continued from page 314.)

EXAMINATION OF SWINE AT CHICAGO.

At Chicago, April 21st, a Dr. Paton [newspaper report] is said to have examined *twenty specimens each from four hundred hogs, or 8,000 hogs in all*. The Chicago Academy of Sciences ("Boston Medical and Surgical Journal," vol. lxxiv, p. 136) reports the examination of *thirteen hundred and ninety-four hogs, of which twenty-eight were trichinous*.

Health Commissioner De Wolff, of Chicago, reported (1879) *finding eight out of one hundred hogs* which he had had examined *trichinous*.

My own examinations. (I beg leave to give them in detail, for reasons which will appear obvious to the reader.)

These examinations were not made upon any special lots of hogs, or upon the many hogs in the city as coming from different sources; but on known swine from the slaugher-houses as they hung up in the slaughter-house, directly after they had been killed and dressed.

No attempt was made to discover the exact locality from

which the hogs came, but they were bought principally in Chicago, coming direct to Boston, and, with the exception of about fifty, *were emphatically Western hogs.*

In making these examinations, a stump of the pillars of the diaphragm was invariably used, each piece representing one hog. But three microscopic specimens were made from each piece—a rule I invariably adhere to; hence, if there is any error in my figures, it is in favor of the hogs.

1879.

RÉSUMÉ.

No. of hogs examined.	Trichinous.	Per cent. of infection.
1879	2,701	154
1881, First source ..	2,000	71
1881, Second source ..	2,068	75
1881, Third source ..	2,004	45
Total	8,773	345
		1 : 25

These figures certainly do not serve to support the words of the State Department, that there are "*less trichinæ in American pork than that of any other country.*" They do speak in no uncertain terms, that our Government has an imperative duty which it owes a large national interest, until the original source whence swine become invaded be discovered.

It has been said already that but about fifty of these 8,773 hogs were bought at Chicago; hence, were Western hogs, though killed and examined at Boston. They were purchased at the same yards from which the Chicago packing-houses obtain the pork which our State Department declared to be so "*free from trichinæ.*"

Further, the percentage of infection of the hogs from the three different sources is interesting, but not easy of explanation, but no more varying than that of those examined in 1879 and 1881 from the same source.

This variation in the per cent. of infection between those examined in 1879 and 1881 called forth the following remarks from Dr. Loring, the present Commissioner of Agriculture :

"A veterinarian of New England informed me on the 14th of April last that he had examined portions from 2,701 Western hogs, obtained in Boston, 154 of which he found infected, i. e., one case to each 17 $\frac{1}{2}$ hogs examined. He tells me that he will make a statement to this meeting that he has examined portions of 8,773 Western animals, and has found one case to every 25 animals. *You will see that there is a great difference between his first (April) examination and this one, and his result is so greatly different from the English examination of our hogs, above mentioned, and so much above any known percentage among animals of every other country, that I can not but entertain doubts of the value of his examination.*"*

The English examination spoken of reads as follows :

"*The inspectors of the Veterinary Department examined two hundred and seventy-nine separate portions of swine's flesh, which were sent from Liverpool, and detected living trichinæ in three specimens*" (1 : 93).

Were Dr. Loring anything but a physician, such criticism as the foregoing might be passed as unworthy of notice, but from a physician, who should have some knowledge of the variation in medical statistics, we should expect some other argument than *empty words.*

First, as to the discrepancy spoken of between the results of my examinations, made about a year apart: it is not greater than that between any two lots taken at random in the same examination, nor so great as between very many lots examined on two consecutive days; as, for instance, in my series of 1881, Lot 14 (source the same as in 1879) was

* See letter to Health Congress, previously referred to.

100 pieces, of which NONE were infected, while of Lot 13, 124 pieces, *six* were trichinous.

In two different epidemics of small-pox, the number of deaths is never the same, or even the number of cases. Are we then to say a later invasion is not small-pox, because the number of cases or deaths is less or more than in a previous? I never for a moment expected similar results, and should have been as pleased to find none as any one in the country.

With reference to the English examination, 1:93, it is greater by far than the percentage of infection found in the hogs of any other country, and greater than I found in some lots examined by me; for instance, Lots 1, 2, 3, 4 of my third series, 1881, contained, respectively, 105, 45, 65, and 80 specimens, representing 295 hogs, of which three were trichinous, 1:98. Further, we do not know the parts the English examined; had they been pillars of the diaphragm, the per cent. might have been greater.

As to the correctness of my results, I will simply say that Dr. Folsom, of the Massachusetts Board of Health, went over a large part of those examined in 1879, and that competent physicians and a gentleman whom I educated to work with me, whom I can call upon for testimony, continually revised my other specimens as I examined them.

Again, if the Commissioner of Agriculture doubts my results, let him send a competent man or men here, and examine with me the same specimens, be it one or ten thousand, and I venture to say we shall find a percentage of infection larger than that reported in any other country, and large enough to satisfy any one.

Further, the Germans might well doubt the figures of their own examinations, as, from the Prussian statistics, we see the percentage of infection is steadily augmenting.

I wish now to refer to the report of Dr. Jansen T. Payne,* which I have before alluded to, from which I quote the following:

"The method of conducting the researches was as follows: 'The examples procured one afternoon were examined the following day by the aid of a good microscope, capable of magnifying objects two hundred diameters. A low power was found to give greater satisfaction than a high or one could have done, and observers in this field would do well to bear this in mind. When it is taken into account that each of the specimens had to be separated into minute sheets before they were placed upon the stage of the microscope, and consider the number of fibers examined in such cases' (the examined in all 21,600 specimens from 5,400 hogs). . . . it will readily be perceived that it is impossible to make anything like an accurate guess as to the whole number of pieces of muscle-fiber examined.'"

Result: This number examined, 5,400; trichinous, 22.

"By this series of examinations, it has been ascertained that Southern-bred hogs are free from trichinae."

If there is anything I dislike to do, it is to criticise the work of another observer; but one would like to know if two hundred diameters is considered a low power. For myself, when looking for trichinae, should I use such a power,

I should not expect to find many trichinae, but *bona-constrictors*; in fact, many would escape me. The male trichina measures one eighteenth, the female one eighth of an inch, in length—magnified two hundred diameters, what would one have?

Again, dividing specimens into shreds may be highly technical, but eminently unpractical; for with crush-specimens one can easily recognize the parasite, and it is done quickly, while in this way, and such a high power as two hundred diameters, one would be sure to miss many.

I doubt the statement that "*Southern hogs are free from trichinae*" as much as I do that "*corn-feeding*" has anything to do with trichiniasis.

My observations have been made, but not of Massachusetts hogs, at Boston, which is not the place for such work, except so far as the obtaining of the per cent. of infection of hogs slaughtered here goes. We must go West, to the fountain-head. At Chicago it would be possible to examine large lots of hogs which have come directly from the breeder or fattener to the packer. Individual lots could be examined, and traced back to the source whence they came. If found highly infected, it would be easy to go to such places and make all manner of examinations—of remaining hogs, the earth, worms, grubs, etc. *Some unknown living thing lodges trichinae before they enter the porcine organism.* The questions are: *What is it? Where is it? What are its modes of life?*

These things discovered, and they must be, an end can be put to porcine trichiniasis, and hence to human.

Bluffing the attempt to write down an existing fact will only end in ridicule to this Government; *research*, untiring and unceasing, is the only "*cure*"; cost what it will, it will pay far better than governmental lies.

American hogs are much more trichinous than European.

A CASE OF OVARIAN CYST, COMPLICATED WITH POLYPUS UTERI.

By H. C. COE, M.D.,

NEW YORK.

If an apology seems necessary for presenting a single case of ovariectomy, in these days when a series of a hundred hardly attracts attention, it rests in the fact that so variable are the conditions surrounding the operation that no observations bearing on new and possible complications can be entirely without value. With the kind permission of Dr. Emmet, in whose service at the Woman's Hospital the case occurred, the following is cited as an instance of a formidable obstacle which may occur to any operator.

Mrs. M. J., aged fifty, entered the hospital September 15, 1882. Though she had had ten children and *twenty-seven* miscarriages during her thirty years of married life, she had always been in perfect health until two years ago, when she first noticed a small lump in the left inguinal region. The catamenia had been regular, but soon after the patient began to have metrorrhagia, at times excessive, and the periods recurred irregularly, attended with menorrhagia. Six weeks before entrance, after being tamponed for hæm-

* Report of the American Public Health Association, 1881.

orrhage, phlegmasia developed in the left leg. The tumor above mentioned grew slowly until two months ago, when it began to enlarge rapidly, and occasioned severe darting pains in the back and abdomen.

On entrance, the patient was exhausted by repeated hæmorrhages, could not sleep in a recumbent posture on account of dyspnoea, and could retain nothing on her stomach. Examination showed the presence of an immense ovarian cystoma (probably multilocular) growing from the left side. Growing from the cervical canal and filling the vault of the vagina was a fibroid polypus, which bled at the slightest touch. As the indications were urgent, it was decided to remove the ovarian cyst first. After the common preliminary treatment, the woman was operated upon in the usual manner. On the night before the operation a brisk uterine hæmorrhage occurred, which was promptly checked by hot-water injections. There was nothing interesting about the tumor, as it was a simple multilocular cyst, with numerous adhesions to the intestines, which showed on their peritoneal coat evidences of recent peritonitis.

Not to rehearse the ordinary after-treatment pursued in these cases, it will suffice to state that the patient had rather more pain in the abdomen than is usual, and had a pulse of an uncertain character, indicating a tendency to heart-failure. However, as she took a fair amount of nourishment, and the temperature did not rise above 102° F., a favorable prognosis was given. There had been no show of blood from the vagina up to the fifth day, when a movement of the bowels occurred, followed by a slight uterine hæmorrhage. The same thing occurred at night, so that it was thought advisable to give an injection of hot alum solution, the vagina being afterward tamponed. The patient was considerably exhausted, but her pulse remained of fair volume. At three and six the next morning it was necessary to repeat the tamponing. As the bowels still had a tendency to move, the rectal enema was stopped, and opium suppositories given, stimulants being administered by the mouth. At ten o'clock the same day the hæmorrhage began again, whereupon the patient was carefully lifted to the edge of the bed, and the vagina exposed by a duck-bill speculum. Blood was flowing freely from the os externum, along the pedicle of the tumor. The bleeding surface was swabbed with a weak solution of iron, and the vagina tightly tamponed with cotton soaked in the same. The woman was now completely exhausted, with a feeble pulse, and vomited several times, complaining of intense pain in the abdomen. As she could retain nothing, whether given by the mouth or the rectum, brandy was administered hypodermically. Her condition improved during the day, though the evening temperature was 102.5°, and peritonitis seemed imminent. The ice-coil was kept on all night, and acted most beneficially in relieving the abdominal tenderness and controlling the temperature. She had improved so much that the next afternoon (the seventh day after the operation) she was lifted from the bed, placed upon the operating-table, and the tampon removed by Dr. Emmet, who syringed out the vagina with a saturated solution of alum. There was no further tendency to hæmorrhage, and from this time until the twelfth day, when she was removed to the house, the

patient's recovery was rapid, and without an untoward symptom. The abdominal wound (which had been closed with "salmon-gut") had healed perfectly, without suppuration.

Five weeks after the operation Dr. Emmet made a vaginal examination with reference to the expediency of removing the polypus; but there had been no return of the hæmorrhage, and it was thought better to wait until the patient's general condition improved. A month later there had not been that general improvement which had been hoped for. The œdema of the left leg had reappeared, confining the woman to her bed and retarding her recovery. Two weeks after this (injections of carbolyzed water had been given night and morning for two months) a foul watery discharge from the vagina suddenly appeared, and, on examination, the pedicle of the polypus was found to be sloughing. The patient was etherized, and the tumor readily removed with scissors. It was found that the necrotic process had extended to the adjacent posterior lip of the cervix, which presented a curiously hardened feel, strongly suggestive of malignant disease. The diseased tissue was removed as thoroughly as possible.

The operation was not followed by bad results, though the offensive discharge continued.

From this time there was a complaint of constant lancinating pains in the lower part of the abdomen. A week later, examination showed that the posterior lip of the cervix had almost entirely disappeared, the vault of the vagina was hard and resisting, and the whole cervix was fixed. The sharp curette was used carefully, on account of the close proximity of the peritoneal cavity.

The patient was advised to go home at once, as she was evidently failing rapidly in strength, and suffered from severe abdominal pains, while there was a profuse watery and offensive discharge, in spite of local astringent applications and injections. It was conjectured, and with some probability, that malignant disease had developed on the site of the sloughing pedicle. January 14th, four months after entrance, she was discharged, and has not been heard from since.

No definite rules can be laid down in such a case as the foregoing. The question first presented, whether the cyst or polypus should be removed, was, from the urgency of the symptoms, naturally decided in favor of the former, since the metrorrhagia seemed insignificant in comparison with the grave general disturbances occasioned by the presence of the ovarian tumor. Perhaps too little stress had been placed upon the hæmorrhages as a possible complication after the operation. Certain it was, that, though not formidable under other circumstances, occurring in a patient so soon after ovariectomy they rendered the case apparently hopeless. The accident was met as it would have been met in any other case; in fact, there was no time to temporize, and every ounce of blood had to be saved at any cost. The idea had occurred to Dr. Emmet to remove the polypus while the patient was in the cottage, but, as the hæmorrhage ceased, this was not necessary. The result would, doubtless, have been fatal. Again, after the patient had become con-

valescent, the question of removing the polypus arose, and here the criticism may be advanced that the tumor should not have been neglected for two months, and finally allowed to slough away. Was not the danger from such sloughing greater than would have resulted from the comparatively slight operation? Certainly, in case this condition had lasted for any length of time. But the case was kept constantly under observation, frequent examinations were made, and it was noted that there was neither hemorrhage nor foul discharge until the rapid change already referred to. Under these circumstances, it was decided that there was no occasion for interference until the woman's convalescence from ovariectomy should be complete.

The final result was unexpected and inexplicable. Why the sloughing process should have begun and extended so rapidly it is impossible to say. The effect on the patient's health was most marked. From the very day of the foul discharge it began to deteriorate. As to the question of the rapid development of malignant disease, the writer is inclined to be skeptical. Microscopic examinations of fragments of the sloughing cervix uteri were negative. The sections showed fibrous tissue, the meshes of which were crowded with leucocytes. In a few places were cells of an epithelial type, but no trace of alveolar arrangement. Not to quote from the literature of a subject on which authorities are divided, malignant degeneration of fibroids is certainly very rare, and such rapid development is rarer still.

Dr. Emmet suggests that the condition of the cervix might be attributed to the sudden development of sarcoma at the point of irritation. This, too, would be a rare occurrence, and it was not confirmed by the microscopic examination.

[A week after this paper was written, the patient called to see me. She was in fair health, but suffered from occasional darting pains in the groins, extending down the limbs. There had been a constant watery discharge from the vagina, but no hemorrhage. A careful examination showed that the peculiar hardening process before noted was not confined to the cervix, but had extended up the canal to the body of the uterus. The finger passed within the canal encountered a soft, fungus-like mass. A portion of this was detached with a dull-wire curette and examined microscopically. The result was negative. As seen fresh, the tissue appeared to be crowded with round cells, with evidences of an indistinct fibrous basis. Hardened sections showed nothing except disintegrated fibrous tissue, the interior of which was poor in cells.

By this additional clinical evidence the theory of malignant disease is still further strengthened.]

CRIMINAL QUACKS.—Quite a number of so-called physicians have recently been arrested on various charges throughout the country.

In one instance, two traveling "cancer doctors" were held to trial on the charge of homicide for causing the death of an old lady seventy-three years of age, whom they had treated for cancer.

In another case a person was arrested in Philadelphia charged with cheating and obtaining money under false pretenses, and one of his methods was to establish quack medical offices in one city after another and then sell out the business under misrepresentations of its value. He had been quite successful in this until the police interrupted his "practice."

Correspondence.

LETTER FROM BUFFALO.

THE course of lectures has just been completed at the Medical Department of the University of Buffalo, and some fifty-seven honorary (or doctors) were conferred on the graduates. But eight others were nominated to the rank of associate deliverers by the faculty, which was the usual practice by the students. I believe this is the only college where the duties of the curators are not merely nominal. After examination by the faculty, the students pass before these old practitioners, chosen from physicians in the western counties of the State, to have their knowledge put upon the rack. The body of curators can pluck whom it pleases, or even give a diploma to one who did not receive a majority of votes from the faculty, as happened at this commencement. A full meeting of the Alumni Association was present to assist at the acconchment. Papers were read before this body upon very interesting subjects—that of Dr. J. B. Andrews, "Practical Remarks upon the Treatment of the Insane," being most interesting. The daily press of Buffalo has, in its endeavors to aid upon the treatment of the insane, the people of Buffalo, been meddling with the treatment of the insane. Hence this well-timed paper of the Superintendent of the State Insane Asylum here. There was another upon the same subject by Dr. P. M. Wise, of the Willard Asylum at Ovid.

The University was founded in 1846, and among the earliest professors in the medical department were men now counted among America's famous physicians and men of letters—Dr. Flint, Dr. Frank H. Hamilton, and Dr. J. C. Dalton, and in the classes have been such men as Dr. Kane, the Arctic explorer, and General Meyer, the meteorologist. The college is very prosperous, and is always generous in endeavoring to secure the best instruction and advantages for her children. Some changes are taking place in the faculty in the lapse of years. Professor C. A. Doremus was recently called to the chair of Chemistry in Bellevue, and, though sorry to lose so thorough and entertaining an instructor, the college rejoices to have obtained so competent a successor in the person of Professor R. A. Witthaus, author of a work on chemistry in the Wood Library. Professor Witthaus is a great favorite with the students. The death of Professor James P. White was a great blow to the faculty, because in him, grown gray with years and large experience, they lost not alone one of the founders of the University, but one who could command the attention of, and instill obstetrics and gynecology into, most unpromising blockheads by his humor and eloquence. His large room, a monument to his great practice, is now the property of the college, occupying a cozy room in the building, and giving students an inviting place to spend their leisure hours these long winter evenings. The place of Professor White has been well filled by Matthew D. Mann, M. D., of Hartford, Conn. Dr. Mann is a fine specimen of one of the most thorough, practical, and conscientious teachers the college possesses. He is a careful and skillful operator, much more scientific and methodic than Professor White, and destined at no distant day to more than fill the place of his predecessor in this special department for western New York. Professor Thomas H. Smith, of Buffalo, who has been in the department here, has been compelled by failing health to give up teaching, and a vacancy has been made in the Department of Surgery in the University of Buffalo. Professor Thomas F. B. Johnson has filled the place of Professor Smith for some twenty years, and there are some who are not likely to enter

to him. In general surgery it has well been said that there is no other clinical teacher in the United States equal to Professor E. M. Moore, of Rochester, and it is the fortune of this University to possess such a Koh-in-noor. In addition to these and the chairs of Physiology—filled by Professor Mason, of Norwich, Connecticut; of Anatomy, by Professor Charles Cary; and of Materia Medica and Therapeutics, by Professor E. V. Stoddard, of Rochester—there are courses of lectures on Skin Diseases by Dr. B. Folwell; on Psychiatry by Dr. J. B. Andrews, Superintendent of the State Insane Asylum; on the Eye and Ear by Dr. L. Howe; and on Pathology and Morbid Anatomy by Dr. Frederick Peterson.

Buffalo, a city of nearly two hundred thousand inhabitants, should and does afford a large amount of clinical material—not so much, perhaps, as with better arrangements might be obtained—still, sufficient to make this city attractive to students and graduates as fast becoming a medical center. The Buffalo General Hospital, with one hundred beds and an elegant amphitheatre, furnishes considerable material for the medical, surgical, and gynaecological clinics. There are three internes, who, without other salary than board and rooms, serve eighteen months each, a new one being chosen every six months from students or graduates of the medical department of the University here. The Sisters of Charity Hospital is larger than the Buffalo General, and provides excellent clinical instruction. There is in this institution no regularly chosen interne, but any student having influence with the sisters can avail himself of residence there and the enjoyment of a large amount of experience. Three or four miles from the city is the Erie County Almshouse, a very large institution, whence comes an all-sufficient supply of anatomical material, affording one of the best fields in Buffalo for clinical experience. There are three internes—one in the chronic insane department with a salary of \$700, one in the general department with \$600, and an assistant to the latter, who has his board. There being but one attending physician from outside, here the internes hold absolute sway over innumerable operations—surgical, obstetrical, medical, anatomical, and pathological. Political influence is necessary to secure these positions.

The magnificent pile of brown stone within two years erected by the State of New York for some of her insane has room for three hundred inmates. Professor J. B. Andrews is the superintendent, with at present two assistants. As the number of patients increases, the number of assistants must rise in proportion. There is always a place there for one student a few months, who wishes to undertake the duties of an apothecary as well as general assistant while attending lectures in the college. It is hoped and expected that we shall soon have the benefit of a clinic on Psychiatry. The Buffalo Eye and Ear Infirmary, under the charge of Dr. Howe, supplies students of that specialty really exceptional advantages, owing to the German element in Buffalo making up one half of the population, and the Germans being by education always more ready than others to patronize public medical institutions. Until within a few weeks this was the only dispensary in Buffalo, but a change as if by magic has come over the spirit of the profession, and now Buffalo enjoys the advantages or disadvantages of at least nine dispensaries either forming or already under way! The laity, which for a moment possibly wonders at this sudden outburst of enthusiasm among doctors for doing good to the poor, thinks truly indeed

"The charities which soothe and heal and bless
Are scattered at the feet of man like flowers."

Alas! were the veil drawn away, how they would be startled at the skeleton behind it! Under the pretense of charity the

physicians thus seek to advertise their names to the public, and jealousy has caused the dispensary mania to become epidemic, no one wishing to be outdone by another in the scramble for vast acquaintance.

But the life which has lately taken the place among Buffalo doctors of this former something—which seemed very much like apathy—has manifested itself, too, in other than selfish directions, in a real determination to improve the general interests and culture of the profession. This has been most marked in the founding of a medical library, which, in a central situation, with several hundred volumes, and innumerable medical journals, American, English, French, and German, now is a magnet to attract the leisure evening hours of the younger proselytes of Hippocrates.

Still, with this the commotion among us has not ceased, for a new medical journal, in German and for the German-American physicians, has just appeared, in addition to the hale old "Buffalo Medical and Surgical Journal," which has hung on to the bosom of the profession for some twenty-two years; and it is somewhere rumored that another and more enterprising one will soon apply its mouth to the nipple of the medical public.

Buffalo has been a Sleepy Hollow, out of which no one has ventured until lately. Years ago some of the physicians had the temerity to go to New York and Philadelphia and bring out to us new ideas and appliances. Several have actually gone to Europe and returned with their heads full of bacteria, which many in the community recognized as of a dangerous septic nature. But the contamination of these is not equal to that of the Hamburg Canal. I ought to speak of the Hamburg Canal at some length. It does honor to the city authorities. It leads one to favor highly the Board of Health's remaining a political body. The Hamburg Canal is that part of the Erie Canal which lies in the city of Buffalo. The city authorities, a great many years ago, wisely arranged that the sewers of the city should empty into this canal. Consequently, we now enjoy the fruits of their wisdom. The odors from this pleasant spot in the midst of the city are wafted into our dwellings along with here and there stray germs of scarlet, typhoid, and intermittent fevers, diphtheria, influenza, etc. Then flowing slowly down to Tonawanda and other villages, the inhabitants there bless us for so generously manuring their soil and drinking water. About a week ago, owing to heavy winds from the lake, in some manner not to my ignorance explicable, our houses were supplied with a rather turbid mixture of sewage from the Hamburg Canal and our clear Niagara water. As a result of this, zymotic and diarrhoeal diseases increased within a few days to a very great extent.

Speaking of the Hamburg Canal reminds me of the new College of Physicians and Surgeons here—which not long ago the Erie County Medical Society destroyed by litigation, but which, like Phoenix, arises anew from her ashes—the thought of one leads naturally to the other. I do not mean to imply any relationship in quality, characteristics, or sensations imparted, but only that the new medical school is situated upon the canal. Being eclectic, as such schools generally are, it teaches homoeopathy chiefly, as such schools generally do. What clever forethought on their part in the choice of situation? Hamburg Canal water, or drops, as they might be called, can so conveniently be applied to the treatment of the diarrhoeal and zymotic diseases—*similia similibus curantur*. However, it seems in some respects unlucky that the faculty of this new institution should have chosen this position for it—and they have our hearty compassion—for already in the streets one hears it familiarly dubbed the Hamburg Canal College.

The interest in medical societies has also been manifestly

awakened of late; the attendance is much larger than of old; papers are newer and better, and discussions more spirited.

The Buffalo Medical Association meets once a month. At the meeting this week we had a paper of unusual value, "Oology in relation to Sanitary Science," by Dr. Julius Pohlman, of the Society of Natural Sciences.

The Medical Club is an association of some twenty-five of the young and active physicians of Buffalo, which meets twice monthly to read and discuss papers, make clinical reports, and exhibit specimens. It is said that the attendance here is always full.

Another club of like character upon the east side of the city is the Medical Union, and there also it is said that a lively interest in the progress of our science is taken, and that papers of much value are read and debated with animation.

The Microscopical Society has a large medical membership. The president of the Society of Natural Sciences is also a medical man, with a catholic love for all science.

We Buffalo doctors are fully alive, as I have shown, to the spirit of these times. Buffalo will one day be a great medical center, as she will be too in all the arts, the sciences, and commerce. At present she rubs her eyes, like Rip Van Winkle, after her sleep of many years.

Book Notices.

Leçons cliniques sur l'épilepsie: Leçons faites à l'Asile Sainte-Anne. Par M. V. MAGNAN, Médecin en chef à l'Asile Sainte-Anne, etc. Recueillies et publiées par M. le Dr. MARCEL BRIAND, Ancien Interne et Médecin Inspecteur Adjoint des Asiles d'Aliénés de la Seine. Paris: Bureaux du Progrès Médical, 1882. Pp. 87.

This brochure consists of a series of six brief clinical lectures upon the subject mentioned, and does not call for an extended notice. Beginning in the first lecture with the *aura*, the writer devotes another to a description of the phenomena observed during an attack, considerable attention being paid to the subject of arterial tension. Several sphygmographic tracings are appended. In the third and fourth lectures the responsibility of epileptics is considered, M. Magnan favoring a mild, but judicious, restraint in the case of those patients who are temporarily dangerous. In the concluding lecture, on treatment, the usual list of remedies is presented, preference being given to the bromides. The easy, conversational style of these lectures makes them pleasant reading. While not assuming to treat exhaustively either the pathology or clinical appearances of epilepsy, they present a fair picture of the disease, as seen from the stand-point of the alienist.

Fragments d'ophtalmologie pratique. Blépharite. Granulome palpébral. Conjunctivite purulente des nouveau-nés. Conjunctivite granuleuse. Kératite vasculaire d'origine granuleuse. Par le Docteur S. BALDEY, Médecin-Oculiste du Bureau de Bienfaisance de Lille. Paris: O. Berthier, 1883. P. 66. [Price, 2 fr., 50.]

This little brochure treats of various chronic affections of the conjunctiva and cornea which are most commonly met with, such as blepharitis, palpebral granuloma, purulent conjunctivitis of new-born children, granular conjunctivitis, and vascular keratitis from granular lids. There is nothing new in the presentation of these subjects or in the methods of treatment proposed. In the purulent conjunctivitis of infants, the author

recommends the daily application of powdered iodoform to the conjunctiva, as well as an ointment of the same; but calls attention to the care necessary in its use, from the danger of poisoning in such subjects. In the vascular pannus occurring with granular lids, he speaks highly of the efficacy of the new Brazilian drug known as jequirity in clearing up the opacity and curing the granulations, and regards it as superior to inoculation.

Simulation de l'amaurose et de l'amblyopie: des principaux moyens de la découvrir. Par le Docteur S. BAYLE, Médecin-Oculiste du Bureau de Bienfaisance de Lille. 5 figures dans le texte. Paris: O. Berthier, 1883. Pp. 32. [Price, 2 fr., 50.]

THE author first considers unilateral simulated amaurosis, and the tests by the prism, strong convex glasses, Javal's method of introducing a pencil or ruler between the healthy eye and the object looked at, Snellen's test of making the patient look through a colored glass, and the stereoscopic test. He calls particular attention to the necessity of carefully observing the direction of the visual axes and the condition of the pupil in these cases. He then considers the subject of unilateral simulated amblyopia, regarding it as important to settle definitely the following three questions: 1. Is the amblyopia real, and of what degree? 2. Is it of traumatic origin? 3. Will the amblyopia remain stationary, or end in absolute blindness? He discusses Herter's test, Monoyer's stereoscopic test, and the test by prisms. The subject is well presented and clearly discussed.

BOOKS AND PAMPHLETS RECEIVED

Manual of Gynecology. By D. Berry Hart, M. D., F. R. C. P. E., Lecturer on Midwifery and Diseases of Women, School of Medicine, Edinburgh, etc., and A. H. Barbour, M. A., B. Sc., M. B., Assistant to the Professor of Midwifery, University of Edinburgh, etc. Volume II. With one lithograph and two hundred and ten woodcuts. New York: William Wood & Co., 1883. Pp. xiii+366. [Wood's Library of Standard Medical Authors.]

Transactions of the Twenty-ninth Annual Meeting of the Medical Society of North Carolina, and Conjoint Session of the North Carolina Board of Health, held in Concord, May 9-11, 1882. Wilmington, 1883. Pp. iii+193-lxvi.

Twenty-ninth Report upon the Births, Marriages, and Deaths in the State of Rhode Island, for the year ending December 31, 1881. Prepared by Charles H. Fisher, M. D., State Registrar of Vital Statistics. Providence, 1882. Pp. viii+157.

Fourteenth Annual Report of the Trustees of the Willard Asylum for the Insane, for the year 1882. Albany, 1883. Pp. 34.

The Percentage of College-bred Men in the Medical Profession. A paper read before the American Academy of Medicine, at its annual meeting in Philadelphia, October 27, 1882. By Charles McIntire, Jr., M. D., of Easton, Pa. Philadelphia, 1883. Pp. 18.

THE HOT SPRINGS OF ARKANSAS.—The Hot Springs correspondent of the "Army and Navy Journal" announces that the springs are "run by the devil," . . . and that "he looks his own trouble," so that those who come and receive no benefit find assured of their future welfare."

YELLOW FEVER IN THE EAST.—The "Gazette de l'Hygiène" de médecine et de chirurgie" remarks that the latest news from Senegal is to the effect that the prevalence of yellow fever has entirely ceased, that Dakar had been free from the disease some twenty days, and that the sanitary conditions of the Port were excellent. A fatal case of the death having been due to the fever that fever that always rages on the African coast.

NEW YORK, SATURDAY, MARCH 24, 1883.

THE UNITED STATES MEDICAL COLLEGE.

AN interesting decision as to the status of medical colleges has just been rendered by Judge Van Vorst in the Supreme Court of this city, upon the following facts: In April, 1882, the Attorney-General of the State, upon the complaint of the New York County Medical Society, brought a suit against Robert A. Gunn, Benjamin J. Stow, Paul W. Allen, Alexander Wilder, Thomas A. Granger, Mark Nivison, and Dennis E. Smith, as incorporators of the United States Medical College, of this city, to set aside the incorporation of that institution. The defendants demurred to the sufficiency of the complaint, but, after the passage, in June, 1882, of an act by the Legislature legalizing the incorporation of "scientific" and "literary" colleges, the demurrer was withdrawn and this act set up in full answer to the complaint, as it was supposed. The plaintiffs in their turn demurred to the answer, maintaining that the act of 1882 was not broad enough to include a medical college.

The fact of the informality of the original organization of the college seems to have been in form admitted by the defendants, and the decision of the Supreme Court in the case of *The People vs. Cothran*, decided in June, 1882, and reported in 27 Hun's Reports, page 345, is to the effect that a medical college can not be organized under the laws of 1848. This latter decision has not yet been reversed, and, as matters stand at present, it is the law of the State. The question involved in the case of the United States Medical College is, whether the act of 1882 legalizes the informal organization of the college under the laws of 1848. This point the Court decides adversely to the college. Section 2 of chapter 367 of the laws of 1882 is as follows: "All scientific and all literary colleges and universities, organized under said acts" (1848), "which shall have reported to the said regents within the two years last past, are hereby declared legally incorporated, and all degrees heretofore and hereafter conferred by them are declared valid; and all such colleges and universities shall be subject to the same duties, obligations, and liabilities, and to the same control and visitation of said regents, as colleges and universities chartered by said regents." The Court, in construing this section, decided that the words "scientific and literary colleges and universities" did not include any other institutions than those referred to in the act of 1848, and that the section was no broader. If, therefore, the act of 1848 excluded medical colleges, they could not be relieved by the later act.

Judge Van Vorst, in concluding his opinion, says: "But upon careful consideration of the subject, after examination of the opinions above referred to and the statutes themselves, I

conclude that the act of 1882 was not intended to and does not include a medical college. And that when its second section speaks of all scientific and all literary colleges, terms used in the amendments of 1870 in a special connection, it refers only to such institutions as could be organized under those acts. I am quite sure that, if some persons had taken steps to organize a corporation under the acts in question for purposes not thereby authorized, the act of 1882 could not be invoked to uphold it.

"The *People vs. Nelson*, 46 New York, 477, holds that, 'in order to avail themselves of that act' (chapter 319 of the laws of 1848), 'parties seeking incorporation must bring themselves within the terms of the act.' And under the decision in *The People vs. Cothran* this the defendants have failed to do. If within its terms, notwithstanding a want of conformity to certain statutory provisions with regard to form of organization or otherwise, its creation would have been legalized by the act of 1882. The question is not free from doubt or difficulty, but I accept the decision already made as the law in this case, and the result reached is, that there must be judgment for the plaintiff on the demurrer."

It is understood that an appeal will be taken by the United States Medical College, first to the General Term of the Supreme Court, and then to the Court of Appeals, if the present decision is sustained. The final determination of the case is, therefore, a matter of uncertainty; but two decisions have been rendered adverse to the position claimed by the college, and it is not likely they will be reversed. Medical colleges have been usually organized, in recent years, under the act of 1853, which contained carefully prepared provisions for their management, and for the graduation of students; but the United States Medical College, which was organized in 1878, professed to be incorporated under the act of 1848, which is totally without any provisions for the proper supervision of any institution such as a medical college. The practical effects of the decision can hardly be stated at present while the appeals remain undecided, but we may indulge the hope that the success thus far met with in opposing the validity of the degrees conferred by this "college" may lead the profession in this State to shake off the apathy with which they have heretofore looked upon the efforts of the county societies toward purging the community of unworthy sources of diplomas.

COLLEGE-BRED MEN IN THE PROFESSION.

A FEW years ago a medical society was organized in this country under the style of the American Academy of Medicine. Fault enough was found at the time with the working of the American Medical Association, and has since continued to be found with it—with ample reason, we are constrained to say. There has, then, been no lack of opportunity for the formation of a national society representing the best elements in the profession of medicine. For some reason, the American Academy of Medicine, which appeared to have been organized with such a purpose in view, failed to impress medical men in general with a sense of its fitness to supplant the older association,

mainly, perhaps, because the latter, with all its shortcomings, was looked upon far and wide with a feeling akin to veneration and affection. It had done good work in the past, and among its permanent members were numbered nearly all the men who were recognized as having contributed to whatever of renown American medicine may deserve. Moreover, most men incline to strive for the renovation of an existing institution, even if it seems verging on decay, rather than begin anew. Attaching all due importance to this consideration, however, we are inclined to think that some other factor must have played an essential part in hindering the academy from springing at once into leadership among our national societies.

We are not sure that this factor was not the very feature on which the academy has seemed to pride itself, namely, that restriction in the matter of eligibility to membership embodied in the policy of admitting only men who had been pupils at an academic college before they studied medicine. It may very well have seemed to many reflecting persons that the academy had missed the substance, and seized upon the shadow. There must be very few persons of intelligence, and of any considerable observation of what is going on in the world, who feel themselves in the slightest degree beneath a man simply because that man is a college graduate, for they know full well that it is within the power of almost any pigmy to perch himself on that Alp. It is not our purpose to join in the cry against American colleges, for we recognize the high order of work that is done by our leading institutions of learning, and we believe that even the lowliest of them serve a good purpose in their respective spheres. Furthermore, we are quite of the opinion that no young man, especially if he intends to enter upon a career in one of the professions, should suffer any prospect of immediate advantage to divert him from securing the great gain that will ultimately be his if he takes the college course. No man, whatever his character or his attainments may be, can take that course without being benefited by it; and this is the same thing as saying that, other things being equal, a college-bred man is the superior of a man who has not enjoyed that training.

Still, it seems to us preposterous to say that he who took the degree of bachelor of arts twenty years ago had a better preliminary training for medical study than he who has recently prepared himself for the college course, but, for one reason or another, has not taken it; or to say that he is any more qualified for membership in an organization that aims at raising the standard of medical education in this country. We can not suppose that the founders of the American Academy of Medicine entertained ideas radically at variance with this view of the matter, but it was quite natural that they should think it desirable to specify a definite criterion, even recognizing the full extent of its fallibility. But the natural course is not always the wisest, and possibly the academy might do as much for the advancement of its purpose as it is doing now, if it were to relax the rigor of its arbitrary test.

One of its members read a paper at its annual meeting, in October last, taking rather a gloomy view of the work to be

done in bringing the medical profession to an equality with the professions of law and divinity in the matter of general education. It was shown that there was a larger proportion of college-bred men among clergymen and lawyers than in our own profession, so far as indicated by college catalogues giving the pursuits engaged in by graduates of those institutions. This comparison, however, strikes us as not quite to the point. The real question is, it seems to us, how the medical profession of the present time compares with that of twenty, thirty, or forty years ago, rather than how it compares with other professions. We are inclined to think the college men are entering upon the study of medicine in increasing proportion year after year; and not only that, but that better men, be they college graduates or not, are coming into the profession every year. On the whole, then, while the American Academy of Medicine may have impaired its own importance by the course we have referred to, we are quite of the impression that the cause it aims to serve is making notable progress.

THE PASSENGER STEAMSHIP MEDICAL SERVICE

DURING the last few months, several of our English contemporaries have commented with a good deal of vigor, and certainly with the greatest justice, on the parsimony which the great Transatlantic steamship companies display in dealing with the medical officers of their passenger vessels. They have also presented to their readers abundant statements of fact, largely in the form of letters from ships' surgeons, on which to found their pleas in behalf of this much-enduring and long-suffering class of men. It is no doubt largely due to this action on the part of the London medical journals that the British Board of Trade has begun to stir in the matter. The result will probably be, that the position of medical officer on board these vessels will be made somewhat more bearable. We wish we could add that it was likely to be made what it should be, considering the importance and the arduous nature of the service, and the attainments and character of the gentlemen engaged in it.

Whatever our admiration may be for the mighty and intricate compound marine engine, it is but a dumb machine after all; and yet at least four engineers are ordinarily employed on vessels of the class we refer to. We do not deny that this number of men should properly be kept on duty in the engineer's department; indeed, we have no hesitation in conceding the wisdom and necessity of such a course, provided the machine is expected to perform creditably. What we would call attention to, however, is the incongruity between this wise provision in one department of a ship's company and the utterly inadequate comprehension of the proper habilitation of another, no less necessary, so uniformly shown by shipowners. Not only has a ship's surgeon to satisfy the whims and caprices of the cabin passengers, to soothe them, to tend and to cure them in a thousand ways to mingle gallantry and *bonhomie* with the grave duties strictly incident to his professional work among them, but, in addition, he has often to attend to the multifarious ailments of a thousand or more sleeping passengers, half of whom, however hale and robust they may have been on

undertaking the trip, have the depressing effects of seasickness and homesickness added to the ordinary vicissitudes that attend the health of man, to say nothing of the changed conditions of their daily life and the bewilderment that comes of fear in regard to present dangers and of anxiety in regard to their future career in a strange land. Furthermore, he has to act as dentist and pharmacist, to battle with the cook in order to get proper nutriment served to the sick, and to assume the real responsibility for the sanitary condition of the ship—a responsibility all the more weighty because unattended with any power of command. If things go wrong in the matter of the bill of health, he is held to answer; if they go right, the captain has ordered them.

Taking into account, then, all that is heaped on the medical officer of a ship, all the attainments and discretion that must be his, in order that the duties of his department shall be properly fulfilled, is it not right and proper that he should be adequately paid and decently bestowed? Why should he be lodged in a quarter of the ship unavailable for other purposes, or, being so lodged, be made to harbor an apothecary's shop within his narrow quarters? Many members of our profession cross the Atlantic every year, and they have it within their power to a certain extent to aid in rendering the status of the marine medical officer more consonant with what it should be, mainly by giving the various companies to understand that, other things being equal, their individual patronage, and, so far as their influence goes, that of their friends, shall be given to the line that shows the best provision for its medical officers. We are quite sure that they need but a hint to lead them to this just and fraternal course.

THE MEDICO-LEGAL SOCIETY AND THE CORONERS.

THE Medico-Legal Society of this city, at a recent meeting, decided to adopt the report of its Special Committee on Coroners, which is in the form of a bill, and directed that it be sent to the Legislature at Albany, with a request for consideration and adoption.

The main points of the bill are the abolition of coroners' juries, and the appointment of one medical examiner for every Assembly District in each county, except Kings, where there are to be two for the whole county, and in New York, where there are to be four. These examiners are to have charge of views and autopsies, and are required to report to the Coroner when occasion demands.

The following are the sections of principal interest in the bill:

Section 1. "The County Judge of each county in this State, except New York, shall, on or before the first day of July, in the year one thousand eight hundred and eighty-three, appoint a medical examiner in and for each Assembly District in his county, except in the County of Kings, in which there shall be appointed two for the whole county; and in and for the City and County of New York the Chief Justice of the Court of Common Pleas shall within the same time appoint four of such examiners for said city and county; such medical examiners shall be able and learned in the science of medical jurisprudence, who shall have been in the active practice of their profession for at least five years; such medical examiners shall be selected and appointed without reference to political or partisan consid-

erations, and solely by reason of their fitness and professional attainments for the office."

Section 2. "The examiners so appointed shall hold their office for the term of seven years, and until their successors shall be appointed and enter upon the duties of their office, but they shall be liable to removal by the said judges appointing them, or by their successors in office, for cause shown after service of written charges and opportunity afforded for defense. . . ."

Section 3. "In the Counties of New York and Kings each of the medical examiners so appointed shall receive in full, for all services performed by him under this act, the sum of five thousand dollars per annum, to be paid quarterly out of the treasury of said counties, respectively; and in other counties of the State the said examiners, respectively, shall receive for each view made by him five dollars; for a view and autopsy twenty dollars, and travel fee of five cents per mile to and from the place of view, to be paid by the County Treasurer upon proper authentication of the charges and approval of the District Attorney."

Section 4 provides that the medical examiners in counties other than New York and Kings shall execute a bond with sureties in the sum of \$500, and in New York and Kings Counties they shall execute a bond in the sum of \$5,000.

Section 5 provides that if the Board of Aldermen of any city other than New York and Brooklyn deem it necessary to have a separate medical examiner, they shall so certify to the County Judge, who shall thereupon appoint such examiner.

Sections 6 and 7 give the duties of the examiners, and they are as follows in full:

Section 6. "The Medical Examiner who shall be appointed and qualify pursuant to this act shall make all the examinations as hereinafter provided, upon view of the body of any person reported or supposed to have been slain or suddenly died or dangerously wounded, or to have died from criminal violence, or by a casualty, or suddenly when in apparent health, or when unattended by a physician, or in any suspicious manner."

Section 7. "Whenever a medical examiner shall have notice that there has been found, or is lying within his district, the body of a person dead or wounded, as stated in the last above section, it shall be his duty to visit and take charge of the body, carefully examine the same, and diligently inquire into the cause and manner of the death or wounding, and make an autopsy, if it shall appear to be necessary, to ascertain the cause of death, or whether a crime has been committed, contributing thereto; and if it shall appear to said examiner that there is no reason to suspect that a crime has been committed which occasioned or contributed to the death, he shall thereupon make a careful statement in writing in duplicate, setting forth every fact and circumstance tending to show the condition of the body, and the cause and manner of death, and the grounds of his conclusion, together with the names and addresses of any person or persons by whom such facts and circumstances may be known, which statement so made by said examiner, or caused to be made by him, shall be subscribed by such examiner; and one without delay shall be delivered to the nearest coroner, and the other to the District Attorney of the county, whereupon the examiner shall give the requisite certificate of death; and in case the person whose body shall have been so examined shall appear to have been a stranger or non-resident of the county, and no relatives or friends shall undertake the burial, he shall give order for the burial, and the expense thereof shall be paid upon the examiner's certificate to the reasonableness thereof. If an autopsy shall be made, it shall be so made as to enable a record thereof to be made and preserved, and to show the actual state and condition of all the vital organs, and in full detail,

and shall be reduced to writing, and signed by the examiner making the same."

Sections 8 to 12 provide for the manner in which inquests shall be held upon the bodies of persons whose death has been caused by violence or in regard to which there may be doubts, and requires the Coroner to take testimony as to all the facts and circumstances, and to file a report, together with the testimony, in the office of the District Attorney for the county. Authority is also given to the Coroner to issue process for the arrest of any persons suspected of complicity in the unlawful act or acts resulting in death.

Section 13 is as follows: "The Medical Examiner may, if he deems it necessary, call a chemist to aid in the examination of the body or of substances supposed to have caused or contributed to the death, and such chemist shall be entitled to such compensation for his services as the Medical Examiner shall certify to be just and reasonable, the same to be audited and paid by the Treasurer of the city or county, as the case may require, on approval of the District Attorney."

Sections 14 to 16 provide for the attendance of witnesses and their fees, require any person knowing of the death or mortal wounding of any one to notify forthwith the nearest medical examiner; and allow suitable compensation to be made to any one bringing to land the dead body of a person found in the harbors, rivers, or waters of the State.

Section 17 provides that the Medical Examiner shall take possession of any money or personal property belonging to the deceased, and deliver it to the persons entitled to its custody; and, if unclaimed, such money or personal property is to be handed over to the Public Administrator or County Treasurer, as the case may require.

Section 18 relates to the payment of the necessary expenses connected with each view or autopsy.

Section 19 allows the nearest examiner to make a view or autopsy in case the examiner in the Assembly District where the body is found is unable to make such view or autopsy.

Section 20 provides that the Coroner must be an attorney and counsellor at law of at least five years' practice, and allows the Board of Supervisors in each county except New York to reduce the number of coroners to one, and in New York County to two.

Section 21 forbids the Coroner to practice in any matter arising out of the duties of his office.

Section 22 forbids the interment of any body, except upon the certificate of death, to be granted by the medical examiner having charge of the matter.

Section 23 abolishes coroners' juries, and inquests held by them.

THE NEW YORK MEDICAL MISSION.

THE New York Medical Mission held its annual meeting recently in the rooms of the Young Men's Christian Association. The object of the mission is to combine religious instruction with free medical attendance to the poor, and during 1882 this object was carried out so far as the limited means of the mission would allow. The main dispensary is now at 81 Roosevelt Street, having been removed there in May, 1882, and in August a branch was opened at the Church of the Reformation in Stanton Street.

Since June, 1881, when the first dispensary was opened, 12,614 cases have been treated at the dispensaries, and 2,491 visits paid at the houses of those suffering from disease. The receipts during 1882 were \$2,187.26, and the expenses slightly larger. It is hoped by the managers that a medical mission institute, modeled after one at Edinburgh, for the training of per-

sons to serve as medical missionaries in foreign lands, can soon be established.

The officers of the mission are: Dr. Alfred C. Post, President; Dr. G. A. Sabine and Dr. W. H. Thomson, Vice-Presidents; Benjamin C. Wetmore, Treasurer; Edward A. Jones, Secretary, and Dr. George D. Dowkout, Medical Superintendent. In addition to these officers, the Board of Managers consists of Cornelius Vanderbilt, James Stokes, Robert Hoe, Jr., Anthony M. Cochrane, William H. Hendrickson, Leighton Williams, and Dr. D. B. St. John Roosa, Dr. Alfred L. Loomis, Dr. L. Bolton Bangs, Dr. Richard Holly, Dr. James R. Leaning, and Dr. Francis H. Markoe.

A MALPRACTICE SUIT AGAINST AN ESTATE.

IN New Hampshire, not long since, a suit was brought by a patient against the administrators of a deceased surgeon for injuries alleged to have been inflicted by the unskillful treatment of the surgeon. The suit was dismissed for technical reasons, which will be of interest, as similar cases may often arise. The Court held that, as the action was for personal injuries, it could not be maintained after the death of the surgeon. It is the theory of the law that an action for injury done to property is not affected by the death of the alleged wrongdoer, but can be brought against his legal representatives; but that an injury to the person, as in the case above cited, is of an entirely different character, and does not survive the death of the surgeon who is charged with inflicting the injury. This may seem rather a narrow rule, and it may not be followed in all the States, but it has in it the basis of justice, as there would seem to be little chance of defending such a suit when the most important witness as to the alleged malpractice—the surgeon himself—is dead and gone. The condition of the patient might be the result of other causes besides the unskillful treatment of the surgeon, but it would be difficult to show such facts after the death of the only person fully conversant with the case.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

A STATED meeting was held January 9, 1883, Dr. T. M. MARKOE, President, in the chair.

EXCISION OF THE KNEE JOINT.—Dr. C. T. POORE presented three patients upon whom he had performed excision of the knee joint. All the operations were performed with the circular incision. The antiseptic spray was not used. The wounds were thoroughly washed out with a solution of carbolic acid, one to forty. The bones were sutured together with wire sutures, and drainage tubes passed through the anterior flap around the joint and out through the popliteal space. To secure immobility, the limb was placed upon a posterior splint and a plaster-of-Paris bandage applied from the toes to the groin, an interval being left at the point of operation.

The first patient was a boy, sixteen years of age, with a rather poor family history. He had pulpy disease of both knee joints. In the right the tibia was dislocated backward and flexed at a right angle with the femur. The right knee joint was excised in 1879, and the result was firm union of the tibia and femur, with two inches shortening. At the time of dismissal from the hospital he had quite good flexion of the left knee, and was able to do an ordinary day's work. Last summer he fell and injured the left knee. This was followed by swelling and pain, and it had

left that joint stiff in a straight position. Notwithstanding this, he was able to get about very well.

The second patient was a girl, thirteen years of age, who fell and injured the left knee joint six years ago. The injury was immediately followed by swelling and pain, and six weeks subsequently an abscess formed, which was opened in Bellevue Hospital. She was subsequently a patient at Roosevelt Hospital, where several large abscesses formed about the joint and the lower portion of the thigh and were opened. She left there considerably improved, but with the limb flexed at nearly a right angle. She subsequently was admitted to St. Mary's Hospital, where Dr. Poore operated upon her, in May, 1882, by removing a V-shaped portion of the lower extremity of the femur. There was considerable shortening after the operation, and there still remained a small external ulceration, but no exposed bone.

The third patient was a boy who had suffered with abscess from Pott's disease, and also had osteitis of the head of the tibia which opened into the joint. Excision was performed in the usual way, and there was nothing peculiar concerning the subsequent progress of the case except that on the following day the temperature rose to 105.5° Fahr., but fell to the normal within a few hours, and afterward there were no unfavorable symptoms except the occurrence of a small slough upon one side of the joint, for which Dr. Poore was unable to account. In this case there still remained a small sinus, into which a probe could be introduced, but he was unable to detect any rough bone.

Dr. Poore also operated in another similar case, and expected that the patient would be present, but for some reason was absent. In all the cases the wounds healed promptly, and all the patients were up on the fortieth day.

FIBRO-SARCOMA OF THE PAROTID.—Dr. H. B. SANDS presented a patient who illustrated the fact that, in the case of tumors which are unpromising in character, occasionally the disease does not return after removal, or, at least, for a very long period. This man, now thirty years of age, came under his notice in June, 1870. At that time there was a tumor in the parotid region, which was believed to involve the parotid gland. It was situated upon the right side, occupied the entire parotid region, and formed a rather low but extensive growth, which caused prominence of the ear, was exceedingly firm, and entirely immovable. It had then been growing for about five months. The case was regarded as unfavorable, on account of the rapidity of the growth of the tumor and the extent and firmness of its adhesions to the deep parts as well as to the skin. Dr. Sands decided, however, to attempt to extirpate it. When the flaps of skin had been raised, a small portion of the growth was removed, and was examined with the microscope by Dr. Delafield, who found it to be a fibro-sarcoma. The piece removed contained a large proportion of fibrous tissue, with cell elements of a round shape. The diagnosis was confirmed by the subsequent examination of the tumor after its removal. The tumor extended into the deeper portion of the neck, and was attached to the styloid process, and was so incorporated with the adjacent tissues as to make the operation very unsatisfactory. The lower surface of the skin was invaded by the morbid growth, being completely incorporated with the whitish tissue of the tumor. Notwithstanding the difficulty of the operation, the patient made a good recovery. Some sloughing of the cutaneous flaps occurred, but beyond this no accident followed the operation, and the patient left the hospital six weeks afterward with the wound healed. Before the operation the facial nerve was intact, but immediately afterward the parts supplied by it were found to be completely paralyzed. The paralysis still remained, although hardly noticeable when the features were in repose. Dr. Sands had watched the case with a great deal of

interest, and made his last note about one year ago, at which time there was no evidence of recurrence of the disease. About three months ago the patient discovered some swellings upon the right side of the neck, and now six or eight flat movable tumors could be felt, extending along the posterior edge of the sterno-mastoid muscle down to the clavicle, the largest being about an inch in breadth and length, and about half an inch in thickness. They are very firm, being in this respect like the original tumor. The skin in the neighborhood of the operation seemed to be sound.

TRACHEOTOMY AS A PRELIMINARY TO CERTAIN OPERATIONS.—Dr. CHARLES MCBURNEY read the following paper:

MR. PRESIDENT: While I have nothing that is really new to offer upon the subject which I have chosen, it appears to me that there are some points in connection with it which are worthy of discussion. The operations which are referred to in the title of this paper are operations for the removal of the upper or lower jaws, particularly when these parts are involved in the growth of large tumors; operations for the removal of large or vascular naso-pharyngeal polypi, or of tumors springing from the tonsils, or walls of the pharynx, or tongue, or palate; and also operations which involve the extirpation of the entire tongue, or of the larynx and adjacent parts; in fact, all operations in the course of which considerable risk is run of having blood or diseased material pass into the lungs or stomach. The old method—so frequently made use of before the introduction of anesthetics, and still recommended by some—of placing the patient in the sitting posture, with the head upright or hanging forward, offers certainly very slight advantage. Some of the blood lost will, to be sure, flow out of the mouth; but the tendency of such blood, as it finds its way backward, to pass down the trachea and œsophagus is greater in this position than in any other. Moreover, the difficulty of retaining a patient who is under the influence of an anæsthetic in this position, and the awkwardness in applying artificial respiration, or of doing tracheotomy if suddenly demanded in the course of the operation, and the greater liability to syncope, form very serious objections to it.

Rose's position, or the hanging head, was an ingenious device, undoubtedly applicable to certain cases. Rose placed the patient with the head and neck projecting beyond the end of the operating table, allowing the head to fall so far backward that its vertex pointed to the floor. The naso-pharyngeal cavity thus becomes a cup placed on a lower level than the orifices of the trachea and œsophagus, and blood collecting in it flows more readily out of the nose, provided the nares do not become plugged with clots, than down the pharynx. From this cup-shaped, dependent cavity blood can be sponged and readily removed. This position appears to me to recommend itself in cases where hæmorrhage will probably not be great, and when the seat of the operation is the palate or mouth, as in cases of cleft palate, or when portions only of the jaws are to be removed without external incisions. But in cases where hæmorrhage is very great, or the disease to be removed involves the naso-pharyngeal cavity itself, the Rose position favors the accumulation of blood at the very place where it is most objectionable. Moreover, patients are not infrequently met with who behave very badly when thus placed while under the influence of an anæsthetic, the tension of the larynx and trachea apparently producing a spasm of the glottis, which becomes dangerous if not relieved.

Both the upright and the hanging head positions are exceedingly awkward in the administration of the anæsthetic, it being necessary to remove the cone as soon as the operation is begun, and to interrupt the operation at intervals in order to give more anæsthetic. This last is a serious objection, for not only is the

operation much prolonged, but blood is frequently lost in large quantities while the mouth and nose are concealed from view. The gravity of extensive and bloody operations about the mouth and adjacent parts has been frequently illustrated in the last few years, not a few such operations having resulted fatally to the patient, either at the time of operation or within a few hours thereafter. Moreover, the nature of the diseases for which most of these operations are undertaken requires that they should be performed not only with expedition, but with great thoroughness.

I have myself seen a patient, from whom one upper jaw was being removed, die on the table from the entrance of blood into the trachea, and the cases are numerous where, in the course of similar operations, tracheotomy has become necessary to save the life of the patient. No operation can be looked upon as unnecessary which promises immunity from such dangers.

I do not know who first suggested a preliminary tracheotomy in the class of cases which I have referred to, but to Trendelenburg is due the credit of giving to the profession an apparatus complete enough to be of very great service in such cases. The original device consisted of a very long tracheal tube surrounded in its tracheal portion with a thin rubber bag, which could be sufficiently inflated, by means of a connected bulb, to completely fill the trachea. To the outer end of the tracheal tube an elastic one, several feet in length, was fitted, at the free extremity of which was a reservoir to receive the anæsthetic. The objections to this instrument, as so arranged, were several. In the first place, if the rubber bag was over-distended, which might easily happen, it might burst, or could force its way down so as to close the lower end of the tube. This latter accident occurred to me in one case, and gave considerable trouble. The tracheas of some patients do not bear well the lateral pressure of the bag, violent cough being induced when it is distended. This I have also seen occur. To remedy the first objection, as well as to get rid of the outer bulb, and to obtain greater nicety in filling the trachea, Dr. Friedrich Lange devised the instrument of which I have a model here. Dr. Lange has already shown this instrument to the society. It seems to me to fulfill the indications for either temporarily or permanently tamponing the trachea better than any which I have seen.

Michael, of Hamburg, surrounds the cannula with compressed sponge. Over the cannula and sponge he places a sac of gold-beater's skin soaked in a solution of rubber. A little water having been thrown into this sac, the sponge swells and effectually closes the lumen of the trachea.

Dr. Foulis, of Glasgow, in extirpating the larynx, tamponed the upper end of the divided trachea with a lead cannula, which was surrounded with a rubber ring, thus completely closing the air tube and effectually preventing the passage of blood into it. Dr. Lange recommends in similar cases a leaden cannula surrounded with punk, which material is light, and does not allow of the passage of fluids through it. These cases, however, hardly come under the head of preliminary tracheotomy, the tamponing of the trachea being necessarily done in the course of the operation.

The objects of the preliminary operation are several. Firstly, to prevent the passage of blood down the trachea. Secondly, to facilitate the continuous and safe administration of the anæsthetic. Thirdly, to avoid the possibility of being called upon in the course of the operation to open the windpipe under forced and adverse circumstances. Fourthly, to permit of a continuous, rapid, and complete operative procedure, and thus avoid much unnecessary loss of blood. Fifthly, to secure to the patient after the operation an abundant supply of air which is not contaminated by the discharge from the seat of operation.

The prevention of the passage of blood down the trachea is a danger which always threatens in bloody operations about

the upper air passages, and enough fatalities have occurred from this cause to make it worthy of consideration, death having been produced on the operating table, and pneumonia having been induced in other cases from the entrance of blood into the air cells. The unnoticed loss of blood is, I am sure, in some cases very great when the operator depends upon sponging out the pharynx during the operation, blood passing down the trachea, and more especially down the œsophagus, in large quantities. When the trachea is tamponed so as to permit of a continuous administration of the anæsthetic through the cannula, this loss of blood can be largely avoided, for continuous pressure can be kept up upon bleeding points during the course of a long operation, which, of course, can not be done when the anæsthetic is being repeatedly administered through the mouth and nose.

The continuous and safe administration of the anæsthetic has also the great advantage of not only saving time in operating, and hence some exhaustion to the patient, but permits the operator to deliberately carry out his dissection. In cases of malignant disease, as of the upper jaw, tongue, and pharynx, I am sure that complete extirpation of the disease is far more likely to be attained when the tracheal tube is used than when it is not. Of course, a less rapid recurrence of the disease would then be expected.

The advantages claimed for this preliminary operation can be obtained in a manner somewhat different from, and, in my opinion, better than, that proposed by Trendelenburg. Instead of the long and heavy tube used by Trendelenburg, one very like an ordinary tracheal tube may be used, into the outer end of which the tube to conduct the anæsthetic from the reservoir can then be fitted. It is not necessary to tampon the trachea itself, but this can be very efficiently done by packing the lower part of the pharynx with a sufficiently large sponge, to which a string is attached to facilitate its removal. Kocher recommends this plan, but I first saw this method made use of by Dr. George Peters, and I have seen it used by others, and have used it myself with complete success. It is not perfect, however, for sponge, no matter how tightly packed, will permit of the passage of fluid. I would suggest, as an improvement on the ordinary sponge packing, a sponge about half covered with thin rubber. The rubber side being pushed down and covering the whole lower surface of the sponge, would prevent any drainage through.

There are some questions in regard to this preliminary operation which I am not able to satisfactorily answer to myself:

Firstly, is there any advantage gained by doing the tracheotomy some time in advance of the primary operation? Max Schüller, in his "Monograph on Extirpation of the Larynx," recommends that the tracheotomy be done some weeks in advance, and claims that by so doing the risks of subsequent pneumonia and bronchitis are lessened. Out of fifteen cases of extirpation of the larynx which Schüller collected, five died of pneumonia, and one suffered from severe bronchitis. But I am not able to satisfy myself that any real advantage would be gained by doing the tracheotomy a long time beforehand, except in cases where the difficulty of breathing through the natural passages caused great impairment of health.

In answer to another question, I think a more positive reply can be made.

How long shall the tube be left in position after the operation?

It should, of course, be left in place as long as there is reason to fear that the upper orifice of the larynx may become occluded by inflammatory swelling. But another reason for retaining the tube in position is to enable the patient to obtain a supply of pure air during the suppurative stage. Kocher not only keeps the tracheal tube in, but also the sponge tampon in the pharynx,

the sponge being soaked in a five-per-cent. solution of carbolic acid, and removed only to allow the patient to be fed. This method also enables the surgeon to treat the wound nearly antiseptically, the nostrils being plugged, the mouth closed, though drained with a tube, and frequent washings of the whole cavity being resorted to. I am inclined to think that the comfort and safety of the patient would be increased by following this method in all extensive operations. Michael, Schüller, and others also claim that by keeping up for some time this permanent closure of the larynx, patients are much less likely to suffer from *Schluckpneumonie*, or foreign-body pneumonia. I have myself made use of a preliminary tracheotomy but three times. In one of these the Trendelenburg apparatus gave me great trouble, in consequence of the extreme elasticity of the rubber bag which folded over the end of the cannula when it was distended. In the other two cases for removal of naso-pharyngeal polypi, I made use of a simple cannula, and plugged the lower part of the pharynx with sponge. This method gave me great satisfaction.

Dr. Post said he had performed preliminary tracheotomy three times; twice upon the same subject after a long interval. In two out of the three times the operation was performed without the introduction of the tube according to the method of Dr. Martin, of Boston, which he had found very satisfactory. He introduced a large sponge into the fauces, and only a few drops of blood escaped into the trachea. With the open trachea he found it very easy to sponge out whatever blood might enter. He had found great facility in performing tracheotomy as a preliminary operation, and believed that all the advantages which Dr. McBurney had attributed to the operation were derived from it, and that there was no additional risk from performing it.

Dr. G. A. PETERS had performed preliminary tracheotomy three times. In one case he had used Trendelenburg's tube. Having seen the difficulties which Dr. McBurney had mentioned concerning the use of this tube, Dr. Peters had had the instrument modified, and supposed that he had got rid of the danger, but he then found that another troublesome symptom resulted, namely, a persistent coughing the moment the bag was distended, although he had taken pains to measure the exact amount of air which was necessary to distend the bag up to a certain point. After that he threw Trendelenburg's tube aside entirely, and had since used only an ordinary tracheal tube, stuffing the fauces with sponge. This method had given him much satisfaction. The anæsthetic could be administered without interruption, and he had had no trouble from blood running into the stomach or trachea. In one of the cases where he used Trendelenburg's tube the patient had a cough which lasted for some time, but he attributed it rather to pressure from the instrument than to entrance of blood into the lungs. He had, however, concluded that the most satisfactory method was to use the ordinary tracheal tube and stuff the fauces with sponge.

Dr. GERSTER had performed preliminary tracheotomy once, and in a case previous to excision of half of the larynx. In that instance he used Trendelenburg's instrument, and just after the operation had been commenced the India-rubber bag ruptured. He was obliged to remove the cannula and replace the bag by folds of gauze bound in position by silk. The cannula was then reintroduced, and answered the purpose very well. With regard to one object mentioned by Dr. McBurney concerning tracheotomy as a preliminary operation, his own opinion was that preliminary tracheotomy, performed a good while before the secondary operation, afforded many advantages over its performance simultaneously with the operation for the removal of the disease. He recalled several instances where he had been present and in which considerable time was consumed in performing the preliminary operation; thus, in one instance, half an hour was occupied, and it could readily be seen that in

an anæmic patient the performance of the preliminary operation would necessitate the longer continuance of the anæsthetic, and, therefore, an undesirable exposure to shock. Tracheotomy upon a grown subject was rather an indifferent operation if properly performed and the necessary care was bestowed upon the after-treatment. The operation was not very serious, and the patient's respiratory tract became accustomed to the tube, and he therefore believed it to be advantageous to first dispose of this liability to accident before the operation proper was to be performed.

Dr. W. T. BULL had had occasion to perform tracheotomy as a preliminary operation in four cases; three times for extirpation of a portion of the tongue, and once for removal of a recurrent growth from the side of the pharynx. In all instances he had used the ordinary tracheotomy tube. He had not seen any advantage following the use of the tube with the rubber bag. On the contrary, he had thought that it interfered with expulsion of mucus from the trachea. He had not left the tube in more than forty-eight hours. He regarded the suggestion made by Dr. McBurney with reference to permanent tamponing the trachea after the operation as a very valuable one, and as an important addition in the after-treatment.

Dr. BRIDGON remarked that he had been prejudiced against Trendelenburg's tube, and had simply used an ordinary tracheal tube, packing the fauces with sponge. The operations which he had performed, however, had always been laryngotomies. He thought it unnecessary to make the operation for the introduction of the instrument a tedious one. He believed there was no danger from hæmorrhage, which always ceased after the introduction of the tube. He had been favorably impressed with Nussbaum's method of narcosis in these cases; that is, to precede the anæsthetic by the use of a large hypodermic injection of morphine, perhaps fifteen drops of Magendie's solution. This is to be followed by the use of an anæsthetic, and he had employed chloroform, administering it to the production of moderate narcosis, and then performing tracheotomy. He had been surprised at the small quantity of chloroform required to maintain insensibility. In one operation not more than three drachms and a half were consumed, and the patient was able to assist at the operation, was sufficiently conscious to be able to empty the mouth of blood, etc., and yet he was placed beyond sensitiveness to the knife. He had not seen Trendelenburg's tube used without the occurrence of some disagreeable accident.

Dr. WEIR had performed preliminary tracheotomy in one case with advantage, using only the ordinary tracheal tube, packing the fauces with sponge, and maintaining anæsthesia through the mouth of the tube. He was led to adopt this method because of having previously resorted to Rose's method in the removal of a naso-pharyngeal growth. It was found that the stretching of the neck unduly compressed the trachea and interfered with respiration. In the second case, of a similar nature, the use of tracheotomy permitted more satisfactorily the dependent position of the head. He was, however, loth to adopt preliminary tracheotomy, as a rule, because he believed the operation was associated with considerable risk in itself. He had been led to this conclusion from studying the cases in which the operation had been performed for the relief of syphilitic disease of the larynx without much dyspnoea, and for rest of that organ. In two such cases pneumonia had occurred. He had also seen several instances of cut throat where only the trachea had been incised, and where the patient's condition was good, and subsequently chest symptoms developed. He would not resort to the preliminary tracheotomy unless the subsequent operation was evidently to be an excessively bloody one, and the risks not to be avoided by position, slight anæsthesia, etc.

Dr. SANDS could recall only a single case in which he had used Trendelenburg's tube, and in that instance it worked very well. Pains were taken to prevent the expansion of the rubber bag over the lower orifice of the cannula, and the only inconvenience observed was the occurrence of coughing, as already mentioned by Dr. PETERS. He thought that if the instrument could be used with success so far as to completely occlude the trachea, it would form a very valuable invention. He had noticed, however, that it frequently failed to accomplish the purpose for which it was designed, as it allowed blood to pass down into the trachea. He had many times excised tumors of the pharynx and tonsils, or had removed the upper jaw without encountering the least danger from the entrance of blood into the air passages. He thought that if three points received due attention during such operation, little or no danger need arise from this cause. In the first place, the patient should be placed in a chair with his head inclined slightly forward; in the second place, profound anesthesia should be avoided, as the blood would enter the larynx only when it was rendered quite insensible, as was the case with deep narcosis; in the third place, he thought it was desirable to operate quickly. In two cases of naso-pharyngeal polypus which he had removed some years ago, no blood entered the trachea so far he could discover, and the patients made a good recovery. The principle of tamponing the trachea was important, however, and he would be glad to see it realized in practice. His own experience had not led him to regard tracheotomy as an operation likely to cause pneumonia, yet he was not prepared to deny that such might sometimes be the case.

Dr. GRESTER said that the weight of Dr. Sands's remark was largely in the proposition which he made not to carry the anæsthetic too far. He had had occasion to perform several operations upon the upper jaw, and had always been careful not to place the patient too profoundly under the influence of the anæsthetic; only just sufficiently so that he would not resist violently enough to prevent finishing the operation. In all these cases he had not seen any difficulty whatever, because when any blood entered the trachea the sensitiveness of that tube induced reflex movements which caused an immediate rejection of the blood.

Dr. STIMSON doubted whether the patient could always be depended upon to give evidence of the presence of blood in the trachea by cough. He had one patient whom he had anesthetized six times for the removal of a constantly recurring growth in the upper maxilla. The woman took ether badly, and complete anesthesia was never obtained for more than one or two minutes at a time. In that case he had seen the pharynx so full of blood that air bubbled up through it, and yet the patient never coughed. He was not positive that blood made its entrance into the trachea, but it was in the pharynx in large quantities, and air bubbled up through it. No bad consequences followed.

The PRESIDENT remarked that during the last fifteen or twenty years he had performed quite a large number of these operations, and he believed that by simply bearing in mind the suggestion made by Dr. Sands no difficulty need be experienced with reference to a serious quantity of blood getting into the trachea. He believed that in a large proportion of cases the most bloody operations could be performed with safety without preliminary tracheotomy.

Fracture of the Calcaneum.—Dr. L. A. STIMSON presented a specimen which illustrated fracture of the posterior portion of the head of the calcaneum. He believed it to be probably the result of muscular action. The patient was a man, fifty-three years of age, who was admitted to Bellevue Hospital in November last for a disease of the tibia which required amputation. Eight

years ago, while crossing the street, he was knocked down by a wagon, and received the injury which the specimen illustrated. At the time the injury was received the patient said that the skin was not bruised. The fragment was the portion to which the tendo-Achillis was attached, at least partially. It was more than an inch in length, and about three fourths of an inch in breadth. On its outer side the periosteum was complete; on the inner side there was a growth of bone which presented the appearance of having been the result of reparatory action. The fragment had united with the bone at its upper border, but was about half an inch anterior to its original position. The specimen was accompanied by photographs and a plaster cast which illustrated the deformity.

Dr. BULL thought that pure muscular action could not produce this fracture; that it was the result of direct violence.

Dr. STIMSON remarked that there were several cases upon record in which the fracture occurred as a result of muscular action.

Dr. PETERS referred to a case in which fracture occurred as a result of muscular action.

MELANOTIC SARCOMA.—Dr. A. G. GRESTER presented a specimen of melanotic lympho-sarcoma, which he removed from the neck of a man on the fourth of the present month. Three months ago the patient got heated from running about, and then sat down in front of an open window and was chilled. This was the only fact which he had been able to ascertain concerning the cause of the growth, although he did not attribute much importance to it as an etiological factor. Immediately after this occurred the man noticed a slight swelling at the corresponding angle of the jaw, which gradually increased in size. There was no sore throat following the chilling, nor nasal catarrh. The tumor continued to grow, and he consulted a physician, who proposed to inject tincture of iodine into it. At that time it was about the size of an Italian chestnut. Considerable reaction followed the injection. The tumor did not resume its former size and shape, but continued to grow rapidly, and, after three months, it attained the size of a small orange. It was situated in the upper cervical triangle, below the angle of the jaw. Laterally it was quite freely movable—not so vertically—and the skin over it was attached to the tumor. Dr. Gerster diagnosed lympho-sarcoma of rapid growth, and gave a grave prognosis. Removal was advised. The excision was not difficult. Immediately after cutting through the skin it was noticed that the mass had a peculiar dark color. On account of its appearance, and from the fact that through a slight puncture made by a hook, introduced into its capsule for the purpose of lifting the tumor up, a black material exuded, he did not attempt to remove the tumor from the capsule, but dissected out the capsule and all, keeping well to the outside of the growth. At the lower and inner part of the tumor, where it approached the superior thyroid artery, there was a dense mass of connective tissue of recent inflammatory origin, which had attached the capsule to the blood-vessel, and also inclosed a small bundle of lymphatic vessels. Immediately upon the oozing of the black, muddy material, which presented the appearance of graphite, through the opening made by the hook, he removed the instrument and applied a ligature round the point, carefully cleansed the part, and then proceeded to the dissection, without further assistance of this kind. At the upper and outer angle of the jaw a large number of lymphatic glands were found, which had exactly the characteristics of the tumor itself. They looked like a chain of small blue grapes, and burst as soon as touched. They were dissected away also with some connective tissue by which they were surrounded. When the tumor was cut open it was found to contain a cavity, in which there moved freely a black body that was surrounded by the dark

fluid material already mentioned. Microscopical examination revealed that the growth consisted almost entirely of round-celled pigmented elements, with a very sparse stroma. The mass, which was free in the center, was doubtless the original swelling or lymphatic gland noticed first by the patient in the neck. The thick melanotic envelope inclosing this glandular body apparently represented the degenerated glandular capsule. The wound was closed by a few silver-wire sutures, and healed by first intention. Early recurrence of the disease was to be expected.

FIBRO-MYOMA OF THE SCROTUM.—Dr. W. T. BULL presented a specimen accompanied by the following history: H. C. F., forty-eight years of age, and married, entered St. Luke's Hospital October 16, 1882. He gave no specific history; there was no history of cancer in the family; there was no history of traumatism. About twenty years ago the patient first noticed a small, hard lump, about the size of a marble, in the lower part of the right side of the scrotum. There was neither pain nor tenderness on pressure, nor discomfort of any kind. This mass gradually increased in size until two or three years ago, since which time it has grown much more rapidly. On admission, he complained only of the weight and inconvenience. The scrotum formed a tumor as large as a child's head, the enlargement being on the right side. The skin was normal, with large veins, the tumor was ovoid in shape, and reached upward as far as the external abdominal ring, which was dilated and filled up when standing by a hernial protrusion as large as a goose-egg, which could be easily returned. The surface of the tumor was smooth, but uneven, and marked by several rounded projections which were semi-fluctuating. The right testicle was, on its lower end, softer than the left, and apparently somewhat flattened, but movable in the tunica vaginalis. The circumference of the tumor at its upper limit was fifteen inches, at its lower part eighteen inches and was of firm, elastic consistence, and not at all tender. There was no pain, either from it or the hernia. The patient had worn no support. There were no enlarged glands. Removal was advised. The parts were washed with a solution of carbolic acid (1-40), after which ether was administered. Dr. Bull was assisted at the operation by Dr. George A. Peters and Dr. R. F. Weir. The hernial protrusion was put back and held, the tunics covering the tumor were dissected down to the capsule, and the cord exposed. A strong ligature was placed round the cord two inches from the tumor, and held by the forceps; the cord was then cut across about one inch from the tumor, and it appeared normal, but it was evident at once that the lower end of the hernial sac, which was adherent to the surface of the tumor over a space as large as half a dollar, had been cut across with it. The blood-vessels were ligated with catgut, the wound in the peritoneum was united by continuous catgut suture, the irregular portion of redundant scrotum was cut off with the scissors, a drainage tube was introduced, and the wound was closed with sutures of carbolized silk. Iodoform, peat bags, and absorbent cotton were used in the dressing. The patient was discharged from the hospital, cured, November 13th. The hernial protrusion was diminished in size, and was retained by a truss. The tumor weighed three pounds and a half. It had been examined by Dr. Satterthwaite, who reported that it was a composite growth, consisting chiefly of ordinary fibrous tissue, to a less extent of fatty tissue, and to a still less degree of non-striated muscular tissue. It was situated behind the cord, which was lengthened, but otherwise unaffected, and above the right testicle, which was normal, as was also its tunica vaginalis. The origin of the growth was apparently from subcutaneous connective tissue, its outer layers forming a sac that was infiltrated with lime salts over most of the surface, while, where depositions were absent, there were small hernial protrusions of tumor substance.

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held January 16, 1883, Dr. C. C. LEE, President, in the chair.

NEEDLE FOR THE PASSAGE OF WIRE OR OTHER SUTURES.—Dr. W. M. CHAMBERLAIN described a needle which he had seen used by Dr. Sands in an operation for tying the femoral artery. It was the invention of Colin, of Paris. It involved the principle of Peaslee's needle, over which, however, it possessed certain advantages. The shaft was much more slender, and near the point, which was slightly flattened, was a notch for the reception of the suture. This notch could be covered by pushing home a sliding sheath. The needle passed through the tissues with ease and without laceration, and the suture was placed with the least possible trouble.

The pathologist, Dr. H. J. GARRIGUES, presented the following reports:

I.—ON THE SPECIMEN OF CHILD'S LUNG, presented January 2, 1883, by Dr. DAWSON. The alveoli are in many places filled with round cells. In some, the alveoli have altogether disappeared, and in their stead we find large fields composed of similar cells. In some alveoli the endothelial cells are seen breaking down and forming such cells by endogenous proliferation. The connective tissue between the alveoli is likewise crowded with such inflammatory elements. Nowhere is found a fibrinous exudation. The diagnosis is, therefore, catarrhal pneumonia.

II.—ON SPECIMENS OF FALLOPIAN TUBES REMOVED BY Mr. LAWSON TAIT, presented December 5, 1882, by Dr. T. A. ENNET.

1. The first specimen presents an oval body as large as a hen's egg. It is filled with pus. The wall varies from three to five millimetres in thickness, and is only composed of inflamed connective-tissue fibers interspersed with round cells, and contains neither muscular fibers nor ovarian stroma. The cavity is continuous with the caliber of the Fallopian tube, which is as thick as a little finger, and likewise contains pus. It can be cut open from one end to the other. The lumen is not enlarged. Diagnosis, pyosalpinx.

2. The second specimen is composed of an apparently healthy ovary covered all over with a false membrane, and a piece of Fallopian tube seven centimetres in length. The fimbriae are gone. In the outer half the characteristic longitudinal folds of the mucous membrane are still visible. The inner half forms a sac of the size of a pigeon's egg, with very thin walls. It communicates with the other half, but is otherwise completely closed. It contains a thick, grumous fluid, in which no organic elements can be recognized. Diagnosis, hydrosalpinx, perioöphoritis.

3. The third phial contains four pieces:

(1) A piece about four centimetres long and as thick as a little finger. Cut open, it shows various cysts of different sizes, from that of a pea to that of a small nut. Microscopical examination shows connective tissue with many arteries like that found in the interior of the ovary near the hilum. (2) A larger body of the size of a hen's egg. The cut surface shows small cysts with coagulated contents, and holes which look like the lumen of a very much contorted tube. Microscopical examination shows that the tissue is chiefly composed of smooth muscle fibers. This piece seems, therefore, to be a much changed part of a tube. It is not the ovary. (3) A cylindrical body, as thick as a finger, bent together at the ends. Cut open, it shows the folds of the mucous membrane of the tube. (4) An oval piece, of the size of a small hen's egg. It is chiefly composed of a large cyst, with thin, smooth walls, and thick, grumous contents, without formed elements. Another part shows what seems to be the lumen of the tube surrounded by the foldings of the mucous membrane. Diagnosis, hydrosalpinx.

VARICELLA SIMULATING VARIOLOID.—Dr. B. F. DAWSON reported a case of varicella occurring in the Foundling Asylum, which simulated varioloid so closely that it was mistaken for that disease by himself and Dr. Delafield. The symptoms for the first three days were those of varicella; they then became much aggravated; the eruption took on a pustular form and became umbilicated. The cutaneous lesions of the disease which afterward broke out among some of the children inmates of the institution presented the same pustular and umbilicated form, but the other symptoms were not aggravated, being purely those of varicella. He inquired if similar cases had been seen in the city recently.

Dr. A. S. CLARKE said that at Christmas time he was called to see a boy in Brooklyn who was suffering, as it was finally determined, from varicella, the eruption of which on the fourth day was exactly such as Dr. Dawson had described. The rest of the symptoms, however, were not aggravated, nor were they in other children of the family who took the disease.

Dr. H. T. HANKS remarked that two or three years ago he treated a child in whom an eruption resembling that of varioloid broke out just before the desquamation following an attack of scarlet fever should have occurred. A well-known dermatologist and two other physicians believed, with himself, that the case was one of varioloid. But the examiner from the Board of Health thought it was one of varicella. The subsequent history of the case seemed to confirm the view of the physician from the Board of Health.

THE PRESIDENT had observed that the tendency of the eruption in varicella to take on the pustular and umbilicated form was greater in ill-nourished children than in those who were well nourished and had good hygienic surroundings. This was also true of other skin affections, and the explanation was evident.

Dr. H. J. GARRIGUES remarked that about ten years ago, during an epidemic of variola and varioloid, he sent a vaccinated child, two years old, to the Small-Pox Hospital as a case of varioloid, and it was admitted as such. But the chief physician of the hospital told him afterward that the future history of the case proved that it was one of varicella. The entire body, however, had been covered with very prominent papules, on the top of which there formed quite a small vesicle that resulted in an umbilication.

Dr. F. P. FOSTER remarked that there were several affections which were difficult, so far as the skin lesion was concerned, to distinguish from the varioliform diseases. He believed there were a good many cases in which it was difficult, if not impossible, to make a diagnosis, based upon the skin lesion alone, between varicella and small-pox. Umbilication was of comparatively little importance as a differential sign; it certainly was not confined to the lesions of small-pox. It might occur in varicella, and in purely local diseases. It was not due to the essential nature of the disease, but to the course which the individual cutaneous lesions might take, occurring in those of slow growth in consequence of desiccation of the center during the enlargement of the periphery. According to this view, it was evident that any vesiculo-pustular eruption might undergo a development which would lead to umbilication. There were many features of distinction between varicella and small-pox. Perhaps no single one, however, was pathognomonic. That mentioned by Dr. Garrigues was doubtless the most distinctive—namely, the rapidity with which the eruption developed in varicella, and the fact that the lesion was a vesicle almost from the beginning, whereas in small-pox it began as a papule.

ANTE-PARTUM HÆMORRHAGE.—Dr. HANKS narrated the following cases which he had seen in consultation some time before: The first case was that of a multipara, about thirty-three

years of age, who, at 4 p. m. one day during the ninth month of pregnancy, was taken suddenly, without apparent cause, with profuse hæmorrhage. Dr. Hanks was called at nine o'clock in the evening. Her physician had been unable to check the hæmorrhage, which had continued with occasional intermissions up to that hour. Believing that he heard pulsation of the fetal heart, Dr. Hanks suggested immediate delivery. Ether was administered, the cervix was quickly dilated, by means of his own egg-shaped, hard-rubber dilators, not more than five minutes being occupied, the forceps was applied to the head, and delivery of a full-sized living child was soon effected. The woman had no further hæmorrhage after delivery, and rallied slightly, but died after twenty minutes. The placenta was expelled naturally. On examination, some indications were found which showed that there might have been a slight separation of the placenta from its attachment. But they were not positive. In no other way could he account for the hæmorrhage. The case was of interest: 1. Because a living child was extracted after an alarming and, as it proved to the mother, fatal hæmorrhage. 2. Because it illustrated the advantage of the egg-shaped hard-rubber dilators in cases where a little time might be all-important to both mother and child.

The second case was that of a woman who at the fifth month had profuse hæmorrhage, which her physician attributed to placenta prævia. Hæmorrhage occurred again at the ninth month, when the patient was in labor. Dr. Hanks, being called in consultation, found the cervix considerably dilated and filled by the placenta, which was easily detached from the border of the cervix with the hand. A little chloroform was administered, and extraction by the feet was readily effected. The child lived, and the mother, who had been nearly exsanguinated, also made a very rapid recovery. Dr. Hanks accepted the suggestion made by Dr. Mundé—that it was better to class the second case among those of placenta prævia than among those of so-called ante-partum hæmorrhage.

OVARIAN CYSTOMA TREATED BY PARTIAL REMOVAL AND DRAINAGE.—Dr. JAMES B. HUNTER related a case, which was that of an unmarried woman, twenty-three years of age, who was supposed to be suffering from an ovarian tumor dating back four or five years. The history presented no unusual features. On cutting down upon the tumor, on December 2, 1882, it was found, much to his surprise, to be a cyst firmly adherent behind the uterus, and impossible to remove. About two thirds of the tumor was then excised, some small tumors within the larger one were broken up with the hand, the cavity was cleaned, and the edges of the lower third of the sac were stitched to the abdominal wound, the upper part of which was treated according to the usual method. A hard-rubber drainage tube was introduced, and carbolic water was injected whenever there was any offensive odor. Peritonitis developing, rubber coils, through which cold water passed, were applied to the head and abdomen whenever the temperature rose much above 100° Fahr. The elevation of the temperature subsided at the end of a week, the discharge from within the sac ceased to be offensive, and the patient made a rapid recovery. Peat-bags, which seemed to answer a very good purpose, were employed afterward in dressing the wound. Dr. Hunter said, in reply to a question by the President, that peritonitis seemed to be due to the handling rather than to imperfect drainage. To a question by Dr. Chamberlain, whether any portion of the cavity of the tumor was closed by sutures separately from the abdominal wound, Dr. Hunter replied in the negative.

THE PRESIDENT remarked, with reference to the method of treating the tumor as mentioned by Dr. Chamberlain, that he considered it unsafe. In a certain case in which he closed the lower portion of the sac separately with carbolic-silk ligatures

an abscess formed, free drainage was impracticable, and septic peritonitis developed. The abdominal wound was reopened, but the patient died.

DEATH AFTER TRACHELORRHAPHY.—Dr. P. F. MUNDÉ related a case as follows: Three or four weeks ago a woman entered Mt. Sinai Hospital to be treated for laceration of the cervix uteri and for accompanying cystocele and proctocele. The uterus could be drawn down to the vulval outlet by the slightest traction without producing any pain. The laceration was repaired without the administration of an anæsthetic. The patient did not complain of much pain. After the operation the temperature rose to 104° Fahr., but was reduced to 102° by the use of quinine and ice-water applications to the abdomen. Hot carbolic vaginal injections were given. The temperature then ranged from 101° to 103° for ten days. There was an offensive bloody discharge from the vagina. The sutures were not removed until the eighth day, when union was found to be perfect. The temperature remained between 101° and 102° for several days after the removal of the sutures, but the patient's condition was very low; she complained of no pain. Quinine, opium, and stimulants were administered, but death took place about the fourteenth day after the operation. The autopsy showed general peritonitis. There had been no signs of peritonitis before the removal of the stitches, and Dr. Mundé thought the patient must have been suffering from septicæmia. It was probable, in the light of the autopsy, that there must have been a gradual development of peritonitis from the uterine envelopes upward until it became general.

Dr. HUNTER remarked, with regard to the cause of death in the case of the patient upon whom he had operated for laceration of the cervix, and to which Dr. Mundé had referred, that there was salpingitis, and it was supposed the tube had ruptured, although an autopsy could not be obtained to demonstrate the fact. The uterine cavity was also everted with a sharp curette at the time of the operation for repairing the cervix.

DIAGNOSIS OF URETERITIS BY PALPATION.—Dr. MUNDÉ also narrated this case, which was interesting specially with regard to diagnosis. The patient presented herself last fall with symptoms of cystitis and pain on micturition. The urine contained pus, with bladder epithelium. A prescription of benzoate of sodium and tritium repens gave considerable relief. The patient complained every day for about a week of severe paroxysmal pain extending from the lumbar region on the left side toward the bladder. Considerable opium was required to relieve pain. Dr. Mundé made the diagnosis of possible renal calculi passing down the ureter, but thought it more likely a case of catarrhal inflammation of the ureter. These symptoms disappeared under treatment, and the amount of epithelium from the bladder greatly diminished under injections. About New Year's day Dr. Mundé was again called, and found the patient suffering from all the symptoms of acute indigestion, and about ten days later she again complained of pain in the left groin. Repeated vaginal examinations revealed no abnormal condition until January 11, 1883, when, greatly to his surprise, he felt what appeared like a whip-cord, of about the size of a goose-quill, running from the neighborhood of the base of the bladder upward and backward in the direction of the vaginal pouch on the left side. It was exquisitely tender. The patient was still complaining of pain in the left groin. The urine showed ureteric epithelium and a less amount of vesical epithelium than formerly. Having never before felt the ureter through the vagina, Dr. Mundé asked Dr. Emmet to see the case. Dr. Emmet stated that it was the first instance of the kind which he had seen. They agreed in the diagnosis of ureteritis. Dr. Emmet expressed the opinion that there was vesico-vaginal cellulitis, and that the serous exudation had pressed the thickened ureter

downward, and, in order to confirm this view, suggested that the temperature be taken in this neighborhood per vaginam. The temperature was found to be 103-25° Fahr. It was not taken elsewhere, but it did not seem much elevated.

With regard to the first case reported by Dr. Mundé, Dr. HUNTER said that about two years ago he closed a laceration of the cervix in a very healthy, strong woman, thirty-two years of age, inserting about ten sutures, and three days after the operation a local peritonitis developed, and the patient was very sick, but finally recovered. The sutures were removed three or four weeks after the operation, and union was found to be perfect.

Dr. CHAMBERLAIN said that in Dr. Mundé's case, the sutures having been removed on the eighth day, and perfect union found, septicæmia from the wound seemed improbable.

Dr. GARRIGUES thought it would be interesting, in the light of recent discussions in England upon the danger of the operation of trachelorrhaphy, to know how many deaths had occurred in connection with the operation in this country.

Dr. BACHE McE. EMMET remarked that the only fatal case which had occurred in the Woman's Hospital for a great many years was one in which the cause was directly traceable to exposure to a draught at the window.

With regard to Dr. Mundé's second case, Dr. GARRIGUES remarked that while he had never diagnosed a swollen condition of the ureter by a vaginal examination, he should think it quite possible to do so in such a case as Dr. Mundé had described, in which the location of the cord which had been felt corresponded to the position which the ureter would naturally assume in that state. He then described the relations of the ureter to the pelvic organs as he had found them in recent anatomical investigations.

Letters to the Editor.

CODES OF ETHICS.—A CORRESPONDENCE BETWEEN DR. AUSTIN FLINT AND DR. FORDYCE BARKER.

NEW YORK, March 19, 1883.

To the Editor of the New York Medical Journal:

SIR: Dr. Barker has kindly complied with my request, in permitting me to send you for publication a letter embracing replies to certain inquiries contained in a note to him, which is also inclosed.

[DR. FLINT TO DR. BARKER.]

"418 FIFTH AVENUE, March 17, 1883.

"DEAR DR. BARKER: From the report of your remarks at the meeting of the New York Academy of Medicine held on the evening of March 15th, contained in the New York 'Tribune,' I quote as follows:

"Dr. Fordyce Barker, in opening the subject for debate, emphasized its great importance, but called attention to the fact that no legislative acts were efficient that were either in advance of public sentiment, or were not sustained by public opinion. The influence of all such acts could be only injurious, as leading to disregard and contempt."

"Applying this sound principle to the question which now engages the attention of the medical profession of this State, namely, the question as to the substitution of the 'new' for the 'old code' of medical ethics: 1. Is it not unwise to consider the question as settled by a small plurality of votes? 2. In a matter of such great importance, involving as it does the liability to a division of the profession into two

parties, does not a sound policy dictate that there should be at least some approach to unanimity of sentiment? 3. Is it not best that those who entertain opposing views should be content to await longer deliberation and a fuller expression of opinions throughout the State, with the expectation that there will be a nearer approach to unanimity than is now apparent?

"In venturing to make these inquiries, on the score of a long and intimate friendship, I believe it to be quite unnecessary to say that no one can attribute your action, now or heretofore, to any other motives than a sincere desire to promote the best interests of our profession, and the welfare of mankind.

Very truly yours,

"A. FLINT."

[DR. BARKER TO DR. FLINT.]

"24 EAST THIRTY-EIGHTH STREET

"March 18, 1883.

"MY DEAR DR. FLINT: I thank you most warmly for your kind letter, which I received last evening, and which I will answer most frankly.

"I am in entire agreement with you to the extent that I should answer each of your questions unequivocally in the affirmative, and I will briefly give my reasons for thus answering each of them.

"To your first question I should reply that it is even more important that the new code of ethics recently adopted by the Medical Society of the State of New York should not be in advance of the public sentiment of the profession, and that it should be sustained by public opinion, than in ordinary legislation, because of certain peculiarities in this which do not ordinarily have any influence or bearing on the efficiency of legislative acts.

"To many minds, the new code seems to abrogate, or rather by its silence to release the profession from, certain obligations or duties which all wise and good men in the profession deem imperative; and all such must have the conviction, and act in accordance with the feeling, that moral duties are always obligatory, and that the silence of a code can not release any one from such duties. The question, therefore, must mainly rest upon the point, whether freedom of personal judgment may, under certain conditions, be wise and safe for the profession at the present time. It is not pertinent to our correspondence to discuss this point, but simply to state the fact. The new code makes no new enactments, but adds a new permissive clause, which many deem dangerous to the best interests in lowering its standard of morals and honor.

"Second.—It is not settled by a plurality of votes, because it will not add to the freedom of individual action on the part of those whose honest convictions are opposed to such freedom.

"Third.—I can not conceive that any one would hesitate to answer this question affirmatively, and it is therefore quite unnecessary to assign any reasons for such an answer. I think that we may all rejoice that in this State, for some months to come, the subject is not a question of votes, and can have no taint of medical politics.

"But, as by your kindness I now have the floor, I hope that it will not be regarded as obtrusive or presumptuous if I venture to offer some additional suggestions, not called out by you, but which seem to me pertinent.

"No one can deplore more strongly than myself the fact that the question of the old and new codes in this State has divided the profession in this country into two hostile camps, and has given rise to bitter controversy and personal feelings, which have for the time being interrupted the harmony and good-fellowship of many who are equally actuated by an earnest desire to do their duty to the profession and to the public. But the issue would have to come some time, as the opinions of some men of honest convictions, unquestioned integrity, and earnest purpose, had become so pronounced and potential that the questions involved had to be met and settled. I am so much of an optimist as to believe that the result of the discussion will be for good eventually, in elevating the standard of professional morals in relation to the conduct of physicians to each other and to the public. What is wanted is, a thorough discussion of the principles which underlie medical ethics, in the same spirit and tone which characterize the article in the "New York Medical Journal," as the commencement of a series on

the subject; and the discussion should also include the questions of the utility, expediency, and efficiency of such codes.

"If the wise and good men of the profession, holding divergent views, would unite in such a discussion, in a spirit of candor and honest purpose, would not a greater good be secured than can be attained by public debates in our large medical societies, which almost necessarily involve personal feeling and the imputation of bad motives, and in which the wish to triumph is stronger than the desire to convince? Such debates are productive of little good, as they are invariably tinged with partisan views, and so far commit both speakers and hearers to one side or the other that their minds are not in such a receptive condition as to be influenced by reason and judgment without the bias of personal feeling.

"Is it not possible, in this way, to avoid the danger of an unprofitable, useless, and unfortunate discussion at the next meeting of the American Medical Association, by postponing all consideration of the subject, and appointing a committee of representative men now holding opposing views, to report at a subsequent meeting; and thus secure a 'nearer approach to unanimity,' which you and every one else must desire and hope for. I feel some delicacy in throwing out this suggestion, because, as you know, it has generally been out of my power to attend these meetings, and I therefore may be considered as an indifferent member.

"I remain yours, faithfully,

"FOREYER BARKER."

Very truly yours,

AUSTIN FLINT.

THE HOME FOR CONVALESCENTS.

New York, March 19, 1883.

To the Editor of the New York Medical Journal:

SIR: The managers of "The New York Home for Convalescents," of 433 East 118th Street, have understood that a like institution in another city was lately spoken of in a medical journal as the only "Home" of the kind in the United States. Accordingly, they have asked me, as one of the staff, to call your attention to the fact that a Home for Convalescents under the above name was incorporated in New York in 1880.

When first opened it had only six beds, but, by persistent efforts, the institution being supported entirely by voluntary contributions, the number has now been increased to twenty, and many more could be filled. There is no doubt that this charity gives us that which has been urgently needed.

Miss Louisa Houghton, to whom the honor of establishing the Home is very much due, was moved to the work in consequence of living near one of our wealthiest hospitals. She frequently found sitting on her steps discharged patients, no doubt well so far as actual disease went, yet weak and tired and homeless, without friends to help or work to support them. To such she felt that a couple of weeks rest in some pleasant home would often make all the difference between destruction and a successful life, and she did not rest until her Home was founded.

From the somewhat different standpoint of a hospital resident, I have had an experience fully confirming the need of such a retreat; and while I believe that many charities (either because they are unnecessary or ill-administered, or on account of relieving men of their natural responsibilities) do harm as well as good, I feel that this one, without these drawbacks, is of extreme use.

At present the limited funds of the institution confine its charity to women, and even now there is a small mortgage to be paid off. The managers, however, are anxious to open it to men.

They would be very glad to have physicians or others call at the Home, which occupies a cheerful house in a pleasant neighborhood, feeling sure any visitor will be satisfied with its arrangement and management.

If physicians, with their great opportunities of interesting others, will kindly take a little interest in an institution of such use, and so nearly connected with their own work, the future of the Home will be assured.

Yours respectfully,

SEYMOUR B. COLEMAN,
100 EAST THIRTY-FOUR STREET.

Miscellany.

CHLORAL HYDRATE AS A VESICANT.—Dr. F. D. Ritter, of Gaines, Pa., writes to Dr. T. Gaillard Thomas, as follows: "In complying with your request, I write you concerning my experience with chloral hydrate as a vesicant. Some three years ago I accidentally discovered that when powdered chloral, sprinkled upon ordinary adhesive plaster and melted by a gentle heat (not more than enough to cause the plaster to adhere to the flesh), is applied while warm to the part where the blister is wanted, within three minutes a gentle heat is felt, increasing in intensity for about three minutes more till it is like a burn, then gradually easing off, until, at the end of ten minutes, the parts feel free from pain. The secondary effect is soothing; in some instances within half an hour a second burning is felt, though not so intense as at first, nor so lasting. If, at the end of ten minutes, or as soon as pain has subsided, the plaster be taken off, the surface is found as effectually denuded as by a cantharidal plaster after six hours, though the discharge is not so great. Thus, within ten minutes the work of an old-fashioned blister is accomplished; and the great advantages of the chloral plaster over the cantharidal are: 1st. Its rapidity of action, thus relieving pain, and producing the counter-irritation upon an engorged organ before the congestive action has had time to pass into more than the congestive stage; 2d. Its ease of application; 3d. It need never be taken off to have the blister dressed; but the original plaster may remain until the sore is entirely healed, and the plaster loosens and comes off itself. This is in part my experience, and I would have given it to the profession before, but supposed it was well known."

THE NEW YORK POLYCLINIC has established a reading-room where all the leading medical journals are kept for the use of the physicians studying at that Institution. As further showing the appreciation with which the Polyclinic is meeting, we may mention the fact that it has been found necessary to add a third professor of gynecology to the faculty. We understand that the position has been accepted by Dr. James B. Hunter.

TRANSFUSION OF BLOOD.—Dr. Thomas G. Morton, of Philadelphia, is desirous of securing the histories of all unpublished cases of transfusion of blood which have occurred in this country; and, on application, will be happy to furnish blanks for their registration.—*Med. News.*

THE NEW YORK CODE OF ETHICS.—The "Medical Bulletin," of Philadelphia, thus concludes an editorial article: "The New York State Medical Society is certainly to be congratulated on the settlement of this much-vexed question, at least for the time being. We hope the action they have taken is a wise one. Notwithstanding the ardor with which the question has been argued on both sides, and the professional feelings that such an argument is liable to give rise to, nothing occurred to injure the harmonious relations of the members present. Whatever the reasons that actuated either side, they certainly can not be characterized as sinister or discreditable. We have no reason to believe that either side were actuated by secret motives, and regret that insinuations to that effect have been made. The effect of this action will debar the New York State Medical Society from affiliation with other medical bodies with which it has hitherto worked in harmony, and, as usual, this year their delegates will be refused admission as representatives to the American Medical Association."

It will be remembered that no such delegates were chosen.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.—It is announced that the next annual meeting of the society will be held at Norristown on the 9th of May.

COLUMBUS MEDICAL COLLEGE.—The "Maryland Medical Journal" states that, at a meeting of the Councillors of the Massachusetts Medical Society, in accordance with the recommendation of the Committee on Medical Diplomas, it was voted that Columbus Medical College, of Columbus, Ohio, be dropped from the list of medical colleges whose diplomas are recognized for admission to the society.

PROFESSOR ALBERT SCHÄFER.—M. Albert Schäfer, F. R. S., Fullerton Professor of Physiology at the Royal Institution, and Assistant Professor of Physiology at University College, London, has been appointed Jodrell Professor of Physiology at the College, in the place of J. Burdon Sanderson, M. D., F. R. S., appointed Waynflete Professor of Physiology in the University of Oxford.—*Medical Times and Gazette.*

SMALL-POX AND IMMIGRANT INSPECTION.—The "Sanitary News" addresses good grounds for its fear that small-pox will soon be introduced again into the interior States, especially the West and Northwest, in the absence of proper appropriations by Congress for the work of immigrant inspection.

THE ALBANY MEDICAL COLLEGE.—At the recent annual meeting of the Alumni Association, the President, Dr. Solomon Van Etten, in the chair, an address of welcome on the part of the Faculty was given by Professor J. M. Bigelow. After an address by the President, the following gentlemen were elected officers: President, Dr. Jacob S. Mosher, Albany. Vice-Presidents, Dr. F. S. Greene, Coxsackie; Dr. B. S. McCabe, Greenville; Dr. Daniel Peabody, Springfield, Mass.; Dr. W. W. Appley, Cohecton; Dr. Robert Thomson, Troy. Secretary, Dr. Willis G. Tucker, Albany. Treasurer, Dr. G. L. Ullman, Albany. Historian, Dr. J. B. Stonehouse, Albany. Executive Committee, Dr. Mahlon Felter, Troy, Dr. A. E. Haested, Dr. D. C. Case, and Dr. T. W. Nellis, Albany. A prize of one hundred dollars was awarded to Dr. C. E. Jones, of Albany, for an essay on "Diabetes Mellitus," and the Armsby memorial prize, amounting to the same sum, to Dr. C. B. Herrick, of Troy, for an essay on "The Anatomy of the Hip Joint." The committee recommended the continuance of these prizes for another year, and announced that the prize for the best essay on "Colles' Fracture," for which no competitor had appeared, would be increased to three hundred dollars.

At the annual commencement of the college, the degree of doctor in medicine was conferred upon fifty-two gentlemen. An essay entitled "The Young Practitioner" was read by Dr. Walter Du Bois Hasbrouck. The Curator's report was presented by Dr. S. H. Freeman, commending the class, and congratulating the college on the advantages of the lengthened course. The following themes received favorable mention: "Cell Activity in Health and Disease," by Theobald Smith; "Pleuritis," by John H. Skillicorn; "Intussusception," by Charles P. McCabe.

ACQUITTAL OF DR. FORBES.—Dr. William S. Forbes, Demonstrator of Anatomy in the Jefferson Medical College, of Philadelphia, who has lately been on trial for complicity in the desecration of graves in Lebanon Cemetery, has been acquitted.

THE ASSOCIATION OF AMERICAN MEDICAL EDITORS.—The secretary of the association, Dr. J. V. Shoemaker, of Philadelphia, announces that the next annual meeting will be held in Cleveland, Ohio, simultaneously with that of the American Medical Association, on June 5 and 6, 1883, at 7.15 P. M. At the second session special papers will be read by Dr. John A. Oeterlony, of Louisville, and Dr. Alexander J. Stone, of St. Paul. The subject of the address to be delivered by the President, Dr. N. S. Davis, Chicago, is "The Present Status and Tendencies of the Medical Profession and Medical Journalism." A free discussion upon this important subject is invited, which will be open, not only to members, but to all physicians present. Dr. Marcy's address will be upon the subject of "Journalism devoted to the Protection and Concentration of Medical and Surgical Science in Special Departments."

MALARIA AT ATLANTIC CITY.—In the "Medical and Surgical Reporter" Dr. Boardman Reed discusses the healthfulness of sea-shore resorts, particularly that of Atlantic City, N. J., giving prominence to the question as to whether malaria has its origin there, in the cases of summer visitors, or if the poison, having been imbibed by their systems in the localities in which they live, is not brought to life in many instances by the indiscretions and excesses in which pleasure-seekers are only too apt to indulge at sea-side resorts, such as too frequent and prolonged surf-bathing; too hearty and late suppers, "frequently of raw oysters even in midsummer"; nights of revelry, "with or without a plentiful accompaniment of stimulants," etc. In support of the latter view, Dr. Reed cites several cases occurring in persons in whom

the malaria made itself manifest after their return from other places to Atlantic City, where they had long resided in exemption from such attacks, although he does not attribute these attacks to the pernicious habits referred to.

The initial sentence in Dr. Reed's article, "Is there malaria at any of the resorts along the New Jersey coast?" is negatively answered, by inference, in a quotation from Professor A. L. Loomis, of New York, who says: "Salt-water marshes are, as a rule, especially free from malaria; but mix salt and fresh waters, as in some of the New Jersey marshes, and you have the conditions for generating the poison. Marshes that rest on a substratum of sand are not so malarial as those that rest on limestone, clay, or mud."

Atlantic City "is wholly surrounded by unmixed salt water, besides having six miles of salt meadows behind it, and rests upon a bed of dry sand"—ergo, Atlantic City is of necessity free from malaria, and "physicians, in sending away patients, will do well to bear it in mind."

Besides the causes already assigned for malarial disturbances occurring in visitors to Atlantic City (the permanent residents seemingly enjoying almost complete immunity), Dr. Reed refers to the use of bad water furnished at some of the inferior houses, for which, however, there is now no excuse, as there is an abundance of the purest water to be had, having been proved pure by chemical tests, and continuous use in many houses since last August.

THE DORMITORY SYSTEM IN MEDICAL SCHOOLS.—"We understand," says the "British Medical Journal," "that a proposal to erect a building to contain about eighty sets of residential-rooms, a dining-hall, smoking-room, and committee-rooms, for the use of the students at the London Hospital, is under very serious consideration. The plans have been prepared, and are now awaiting approval. The money necessary to carry through the undertaking is, we are informed, to be raised, on the principle of limited liability, among the friends and the medical staff of the hospital. The scheme seems to be in every way worthy of praise, and ought to be a great boon to the students. Nothing, we believe, will more tend to raise the tone of student life than the multiplication of such residences. At the present time, with the exception of the College at St. Bartholomew's Hospital, and University Hall in connection with University College, both absurdly inadequate to the calls made upon them, there are no residences provided for medical students in London, who, on first coming up to town, are thrown on their own resources to drive such bargains with the lodging-house barpies as their inexperience may allow. Were every medical school provided with a well-planned building, where the sanitary arrangements were good, and the rents and other charges moderate, students would eagerly occupy all the rooms, to the advantage of their health, their morals, and their social position, and to the certain cultivation of more studious habits."

ST. VINCENT'S HOSPITAL.—A new building for this hospital is in course of construction, and we understand that, when it is finished, a change will probably be made in the service of the house staff, so that there will then be a medical and a surgical staff, of three members each. At present one staff has charge of both the medical and the surgical wards.

SULPHUROUS ACID IN SCARLATINA MALIGNA.—Dr. Keith Nobber Macdonald, writing in the "British Medical Journal," denies the prevalent opinion that no reliance can be placed on any drug in cases of scarlatina, and does not hesitate in affirming that, when properly applied, both locally and internally, sulphurous acid is by far the most efficacious remedy we possess. He continues: "I have had several opportunities of testing its efficacy in some of the worst cases I have ever seen, during the epidemic which has been rife in this town (Cupar Fife) for the last two months, and I am bound to say that, of all remedial measures in this disease, it is, in my opinion, the most reliable. My treatment is as follows: The moment the throat begins to become affected, I administer to a child, say of about SIX YEARS OF AGE, TEN minims of the sulphurous acid, with a small quantity of glycerine in water, every two hours, and I direct the sulphurous acid spray to be applied every three hours to the fauces for a few minutes at a time, by using the pure acid, in severe cases, or equal parts of the acid and

water, according to the severity of the case. Sulphur should also be burned in the sick chamber half a dozen times a day, by placing flour of sulphur upon a red hot cinder, and diffusing the sulphurous acid vapor through the room, until the atmosphere begins to become unpleasant to breathe.

"In the worst cases, where medicine can not be swallowed, this and the spray must be entirely relied upon; and the dark sordes which collect upon the teeth and lips should be frequently laved with a solution of the liquor potass. permanganatis of the strength of about one drachm to six ounces of water, some of which should be swallowed if possible.

"In cases presenting a diphtheritic character, the tincture of perchloride of iron should be administered in rather large doses in a separate mixture with chlorate of potash, and equal parts of the same with glycerine should be applied locally, with a camel's-hair brush, several times in the day; but, as in the majority of cases among children it is next to impossible to use a local application more than once, the spray and permanganate solution will then prove of great service.

"As to other remedies recommended by various authors, ammonia is nasty, and can not be taken well by children; carbolic acid has the same fault, and can not be applied properly. Gargles are also useless in children, because they seldom reach the diseased surfaces, and warm baths and wet-sheet packing are dangerous, because they are never carried out properly in private practice. The hypodermic injection of pilocarpine is a remedy that may give good results hereafter, but I have had no experience of its use."

THE MIDLAND MEDICAL MISCELLANY.—The first number of a new medical journal, entitled the "Midland Medical Miscellany and Provincial Medical Journal," has reached us. It is published monthly at Leicester, England. The journal presents a handsome appearance, and its contents are such as can not fail to prove of interest and value to its readers. Its supplementary title is suggestive of the early history of the British Medical Association.

THE LATE GOVERNOR MORGAN'S BEQUESTS.—The will of the late Ex-Governor Edwin D. Morgan has just been filed in the Surrogate's Office in this city, and some of the provisions will be of interest to the profession. The income of one half of the residuary estate, which it is thought will amount to some millions, is given to his grandson, Edwin D. Morgan, Jr., during his life. If this grandson leaves one child, he will then receive one quarter of the said half estate; if he leaves two children, each is to receive one quarter; if he leaves three children, then the whole of the half-estate is to be divided between them. If the grandson shall leave no children, the half of the residuary estate is to be divided into 416 shares, and of such shares a number of medical institutions are to receive the following shares: The New York Society for the Relief of the Ruptured and Crippled, 10 shares; Woman's Hospital of the State of New York, 10 shares; Manhattan Eye and Ear Hospital, 10 shares; Presbyterian Hospital, 20 shares; Protestant Half-Orphan Asylum, 5 shares; New York Juvenile Asylum, 10 shares. The contingency in which these institutions will profit by the bequests is a rather remote one, and many years will probably go by before it will be known how the estate is to be divided.

SMALL-POX HOSPITALS AS NUISANCES.—A recent case in an English court involved the attempt of a property owner to obtain an injunction against the use of neighboring premises as a small-pox hospital. The suit was dismissed on technical grounds, but the judge intimated very strongly that he would have granted the injunction had only the merits of the application come before him.

DR. E. P. FOWLER ON HOMOEOPATHY.—Dr. E. P. Fowler, President of the New York Medico-Chirurgical Society, has favored us with a copy of his annual address before the society. It is a remarkable address—logical and cleverly put together, and the most convincing arraignment of homoeopathy that we have ever read, although written by a reputed homoeopathist and delivered before a society supposed to be made up of homoeopaths. Among other things, Dr. Fowler says:

"It seems hardly possible that any one, previously unbiased, can make a thorough analysis of Hahnemann's 'Organon,' in its entirety, without a conviction that he held disease as being entirely independent

of and different from the ordinary processes characterizing vitalized matter. He apparently looked upon disease, not as a variation of a natural process; he treats of it rather as holding a relation to the human body much like that which genii were once supposed to sustain toward inanimate objects. This is an outline sketch of Hahnemann's system of homeopathy. The 'Organon' explicitly teaches that to cure one disease it is necessary to produce another. The term 'homeopathy' was constructed by Hahnemann, and it etymologically expresses his theory: he was an expert linguist, and would not have coined a term which etymologically misrepresented the idea he wished to express. One disease can be cured only through displacement by another disease: this is the substructure of homeopathy. Hahnemann proceeds to claim that homeopathy differs from all other medical systems in that they have no substantiation beyond theory, whereas homeopathy is a science established by induction—a science *a posteriori*: and upon this ground alone are we asked to accept it. (See Sections 25, 26.) Now, the only material in the 'Organon' which is put forward as inductive facts is to be found in Sections 36 to 46, inclusive. These facts number just thirty-seven—twenty-one to establish as an immutable law that dissimilar diseases do not cure each other, and sixteen to establish the law that similar diseases do cure each other. These thirty-seven citations are simply references; there is not one pretended description among them. With one exception, they are second- or third-handed, and some of them are derived from very questionable authority."

PARKE, DAVIS & CO.'S EMPTY CAPSULES.—The empty capsules made by Messrs. Parke, Davis & Co., of Detroit, are admirably adapted for the administration of nauseous medicines, and deserve to be more generally known. It is much simpler to place the requisite dose in one of these capsules than to make it into a pill, or even to give it in the form of powder. The capsules are made of a pure tasteless gelatine, which dissolves with the greatest readiness. We have given them an extensive trial, and have every reason to be pleased with them. They are made of various shapes and sizes, so that, when filled, they may be given by mouth, or may be used as medicated pessaries or suppositories.—*Brit. Med. Jour.*

WRAPPERS FOR APOTHECARIES.—An ingenious confrère, whose name we regret that we are unable to give, having mislaid his communication, has conceived the novel idea of publishing a sheet, termed "Medical Miscellany," intended for apothecaries to use as wrappers. The printed matter is designed for patients to read. It consists of short ethical injunctions, interspersed with domestic receipts and droll paragraphs on various subjects.

THE NEW YORK OPHTHALMIC AND ACURAL INSTITUTE.—By the Annual Report of this institution, for the year 1882, we find that the field of its usefulness has been enlarged in each of its departments, 6,425 out-patients having been treated, against 5,584 in the year 1881; and 320 in-patients, against 273. The number of important operations performed was 554—an excess of 52 over those performed the year before.

A STATUE OF M. BOULLAUD.—The profession in France are subscribing to a fund for the purpose of erecting a statue of the late Professor Boullaud.

DEATH OF M. LÜER.—The famous Parisian instrument-maker, M. A. Lüer, died recently at his home in Paris.

DEATH OF M. CLOQUET.—On the 23d ult. Baron Jules Cloquet, the last of the founders and a former president of the Académie de Médecine, honorary professor on the faculty of medicine of Paris, honorary surgeon to the hospitals, and a commander of the Legion of Honor, died at the age of ninety-two.

DEATH OF M. BERTILLON.—M. Bertillon, professor of demography at the Paris École d'Anthropologie, and chief of the statistical bureau of the city, died recently, aged sixty-one years.

DEATH OF DR. C. HENRY KING.—Dr. C. Henry King, of Stapleton, Staten Island, died on Sunday, the 18th inst., at his home in Stapleton.

Dr. King was a graduate of the Long Island College Hospital, of the class of 1864, and for a number of years had been the physician-in-chief of the Seamen's Retreat Hospital.

ARMY INTELLIGENCE.—The "Army and Navy Journal" quotes the "Rio Grande Valley" for March 4th as follows: "Last Tuesday evening, at the quarters of Dr. Happersett, U. S. A., at Fort Clark, Texas, was the occasion of a testimonial to Dr. E. Melton, who was employed as an acting assistant surgeon during the late yellow-fever epidemic, and was most assiduous in his attentions to the garrison at Fort Brown during that trying period. Among those invited were many of the prominent citizens of Brownsville and Matamoras, besides all the officers of the garrison."

Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 10, 1883, to March 17, 1883.—BROWN, HARVEY E., Major and Surgeon. Temporarily assigned to duty at Mount Vernon Barracks, Alabama, during the absence on leave of Captain T. A. Cunningham. Par. 2, S. O. 17, Department of the South, March 6, 1883. — WILLIAMS, J. W., Major and Surgeon. Upon being relieved from duty at Fort Cœur d'Alène, Idaho, will proceed to Fort Walla Walla, Washington Territory, and report for duty as medical officer of that post. Par. 5, S. O. 24, Department of the Columbia, March 1, 1883. — CUNNINGHAM, T. A., Captain and Surgeon. Granted leave of absence for twenty days, to take effect from the 21st instant. Par. 1, S. O. 17, Department of the South, March 6, 1883. — HEIZMANN, CHARLES L., Captain and Surgeon. To be relieved from duty in the Department of the South, and assigned to duty at Columbus Barracks, Ohio. Par. 8, S. O. 58, A. G. O., March 12, 1883. — TAYLOR, B. D., Captain and Assistant Surgeon. To be relieved from duty at Fort Ringgold, Texas, and will, so soon as able, report to the commanding officer, Fort Clark, Texas, for duty. Par. 6, S. O. 26, Department of Texas, March 9, 1883. — WOOD, MARSHALL, Captain and Surgeon. Is assigned to duty at Fort Cœur d'Alène, Idaho. Par. 5, S. O. 24, Department of the Columbia, March 1, 1883. — BRECHMIN, LOUIS, First Lieutenant and Assistant Surgeon. To proceed to Fort Brady, Michigan, and report to the commanding officer for duty at that post. Par. 1, S. O. 41, Department of the South, March 14, 1883.

NAVAL INTELLIGENCE.—The "Army and Navy Journal" learns that Medical Director Thomas J. Turner is expected to go to Japan shortly, to study the sanitary system of that country, in connection with his duties as a member of the National Board of Health. — According to the same journal, Passed Assistant Surgeon James E. Gardner recently registered at the Hotel de l'Athénée, Paris. — Passed Assistant Surgeon Howard Smith has been ordered to the Nipic. — Medical Director Edward Shippen has been ordered to duty at the Naval Hospital, Philadelphia. — Passed Assistant Surgeon Richard Ashbridge has been detached from the Miantonomah, and granted leave for six months from March 9th. — Medical Director Samuel F. Coues, recently on duty at the Naval Laboratory, New York, has been placed on waiting orders. — Medical Director Richard C. Dean is to be transferred, on the 31st inst., from the Naval Hospital at Philadelphia to the Naval Hospital at Brooklyn. — Medical Inspector D. Bloodgood has been detached from the Naval Hospital at Brooklyn, and ordered to the Naval Laboratory at New York. — Passed Assistant Surgeon R. A. Urquhart has been detached from the receiving-ship Independence, and granted leave for six months. — Passed Assistant Surgeon Frank B. Stephenson has been detached from the Navy Yard at Norfolk, and ordered to the Navy Yard at New York. — Passed Assistant Surgeon Nelson McP. Fettebe has been detached from the Navy Yard at New York, and ordered to the Navy Yard at Norfolk. — Surgeon Thomas Hiland has been placed on the retired list. — Although it is stated that an error was made in diagnosing the cases of the two sailors who recently died on board the Hartford, in Callao harbor, as yellow fever, a salutary vigilance on the part of the Chilean authorities has been the result, as evinced by an energetic reorganization of their boards of health at Callao and Lima. The health of the Hartford's company is now said to be excellent.

Lectures and Addresses.

A CLINICAL LECTURE ON

EPILEPSY.

DELIVERED AT THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

By WILLIAM A. HAMMOND, M.D.,

PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM.

GENTLEMEN: This is a case of epilepsy occurring in a girl twelve years of age. The attacks date back about two years, occur about three times a month, and are of the *grand mal* variety; that is, she becomes unconscious, falls down, froths at the mouth, bites the tongue or lips sometimes, is seized with general convulsions, and after that goes into a state of stupor. There are different varieties of epilepsy, and some cases differ so widely from others that you would hardly suppose they belonged to the same form of disease. In the milder form of epilepsy there may be no perceptible spasm, although it is probable no case occurs in which there is not any spasm whatever. There may be but a simple twitching of the eyelids, a slight strabismus, or a slight movement of the fingers or of the arm. The spasm, however, is so slight in some cases that, unless it were looked for very closely, it would not be seen. In such a case the patient may be walking the street, or conversing with a friend, and suddenly lose consciousness, only for a moment, perhaps not long enough even to disturb the continuity of his ideas or to stop the conversation. With this unconsciousness, which lasts but a second, there is generally some spasm of the muscles, as of the eyeball or of the mouth, or other part, which the friend may not notice at all. Such is the simplest form of epilepsy, and it may go on for months or years without being observed by anybody but the patient himself, and *he* may not suspect that there is anything very wrong until he feels that his mind is becoming affected. He may then commit some indiscretion which will attract the attention of his friends. Again, the patient may, while sitting at the table, suddenly drop his knife and fork and stare into vacancy, and, after a moment, take up the knife and fork and continue his meal. It is difficult to say whether, in some cases, there is complete loss of consciousness or not, the attack is so short, the patient remembers what was occurring just before the attack, and recognizes what is taking place immediately afterward, and is led to believe that he was at no time entirely unconscious. In this connection I may mention what is called Jacksonian epilepsy, in which there is simply a twitching of certain muscles; it may be of the eye, causing a rolling of the ball, and in which there is no loss of consciousness. Now, I do not believe that such a case is one of epilepsy at all, but that it is simply epileptiform, for the essential phenomenon of epilepsy is absent, namely, loss of consciousness. Dr. Jackson believes that epilepsy may exist without loss of consciousness, but I differ with him regarding that point. Such a case, if not arrested, might pass into true epilepsy, but it is not such at first. This sort of epilep-

tiform disease, in which spasms take place without loss of consciousness, may frequently be produced by irritating different parts of the body. For instance, a man came to me in whom one could always excite convulsions by tickling him in the side. Another patient had an epileptic zone on the top of the head, and if that were touched it would certainly develop an epileptic convulsion; simply pointing the finger in the direction of that particular spot would sometimes bring on an epileptic attack. I proposed to cut off that portion of the scalp down to the bone, feeling confident it would effect a cure, but the patient would not submit to the operation.

Now we come to the next form of epilepsy, ordinarily known as the *grand mal*. The form of which we have just been speaking is called *petit mal*, of which, as you observed, there are two varieties. In the *grand mal* the patient becomes unconscious and falls, generally with the face forward. He may or may not have an aura. By aura we understand a sensation existing in some part of the body which apparently passes up to the brain. I say apparently, because the probabilities are that it passes downward from the brain. When the sensation apparently reaches the brain, the patient becomes unconscious. This aura is found in about one half the cases of epilepsy, and usually consists in a sensation of numbness of some part of the body, often of the right hand; for it is a singular and important fact that, when an aura occurs, it occurs in that part which is most used. If the patient is left-handed, the aura will probably exist in the left hand; but, as most persons are right-handed, the aura is most frequently found to exist in the right hand, and usually in the thumb or fore-finger of that hand, as these are most used. This sensation of numbness, or of tingling, passes up the arm, sometimes rapidly and sometimes slowly, and when it reaches the brain the patient loses consciousness. Another great center for the aura is the pit of the stomach. It may also start from the mouth, the lip, the tongue, or any other part of the body. When the patient becomes unconscious, he falls if left to himself, and, as said before, almost invariably forward. That is a point of some importance in diagnosis when the patient is picked up in the street. Such persons often have scars upon the forehead and face, etc., from injuries received in falling during an epileptic seizure. In about one third of the cases the patient, at the moment he becomes unconscious, utters a slight cry, like the bleating of a goat, and immediately falls. The face, at the instant consciousness is lost, is pale, the sterno-cleido-mastoid and the platysma-myoides muscles then contract upon the veins of the neck and impede the return of blood from the head, causing the face to become purple, sometimes almost black; the muscles of respiration are thrown into tonic contraction, and for a moment the patient ceases to breathe; sometimes the body assumes the position of opisthotonus, but not often. When death occurs during an epileptic attack, it is in the first stage, and is due simply to a want of breath; but this accident is the rarest thing in the world, since the first stage very seldom lasts as long as thirty seconds. Of course, in falling, the patient may receive an injury which

will cause death. After the first stage, which usually lasts five or ten seconds, has passed off, there is a general relaxation of the muscles, the patient takes a long inspiration, the face loses somewhat of its purple hue, but it still remains darker than normal, for the muscles are not yet completely relaxed. The limbs are now thrown into clonic convulsions. The muscles of the face twitch, the head is drawn back violently, the tongue may be thrust between the teeth and be bitten, or, if the convulsive movements occur more strongly on one side than on the other, as they usually do, the inside of one cheek may engage between the teeth and be bitten. This stage may last one, two, or three minutes. If it lasts apparently longer than three minutes, it is probable a succession of fits is taking place. It is very rare indeed that the stage of both tonic and clonic convulsions lasts longer than five minutes. During that period the urine and the feces may be passed involuntarily, but this seldom occurs in the case of grown-up patients. This stage gradually passes off, the breathing becomes regular, the face assumes its natural hue, and the patient passes into a condition of stupor, which may last from a few minutes to several hours. The duration of the period of stupor becomes shorter as the attacks occur more frequently, so that in some of the older cases the patient is able to get up and walk off immediately after the convulsion. In recent cases the mind is confused after the period of stupor has passed by, and there is usually very severe headache. Such is the regular form of the epileptic paroxysm.

There is another variety, which is still more interesting, not only in its medical relations, but also in its medico-legal relations. It is a form in which the paroxysm is aborted. In a case of this kind, which fell under my observation, the patient dropped his work suddenly, seized an ax, and rushed out into the yard and began to batter the fence down. In a few minutes the attack was over, and he knew nothing about what had occurred. Again, he may rise in the night, go into an adjoining room, seize one of his children and throw it out of the window, and, after recovering consciousness, have no recollection of what had happened; or a murder of any kind may be committed during such an attack, in which the movements, though performed voluntarily, are performed during a state of unconsciousness. One of the most remarkable cases of this variety of epilepsy occurred in a large manufacturer in this city, whom I treated some years previously for symptoms due to a syphilitic tumor at the base of the brain. He recovered entirely from these symptoms under the use of iodide of potassium and mercury. Afterward he was brought to me, with the statement that at times he did things of which he was unconscious. On one occasion he went to Easton, Pennsylvania, there got off the car and walked back to New York, where he wandered about for eleven days before he regained consciousness and returned home. During that time he was sought for by the detectives, but could not be found; his conduct was so regular that no one with whom he came in contact suspected in the least that he was unconscious of what he was doing. In another case the patient, a little girl, had fallen upon the street and sustained an injury at the outer and upper angle

of the forehead, which resulted in necrosis and destruction of the cranial bones for about six inches around. The brain was left covered simply by the scalp. Epileptic paroxysms ensued, some of the regular grand mal form, and some of the aborted kind. On one occasion, while I was lecturing upon her case at the University Medical College, she suddenly arose from her chair, walked up to the students and conversed with them about her condition for about three minutes, being unconscious of what she was doing; then, regaining consciousness, she returned to her seat.

It is well to remember that the aborted form of epilepsy may manifest itself in a great variety of ways. This will become evident to you when I state that every disease which is attended with unconsciousness and spasm is epilepsy. This is true, whatever may be the form of the attack, and whatever may be the disease which supplements it. There may be epileptic paroxysms in cases of cerebral hæmorrhage, and in a great variety of affections. The chief symptom in some cases is simply vertigo. A gentleman wrote me from Florida that on one occasion the servants found him before his mother's bedroom door with an ax in his hand, evidently intending to take her life. He was led back to his room, and, when he came to himself, he was suffering from a slight headache, and fell into a deep sleep. His was a case of the aborted form of epilepsy.

With regard to the patient before us, she looks like a bright little girl, and it would appear that the epileptic paroxysms have not yet caused any deterioration of her intellect. However, they do so eventually; but in the case of children a long time is required before it becomes manifest that the intellect is affected. Children sometimes have one or two hundred paroxysms a day, and are just as bright at the close of the day as at the beginning. In illustration of this fact, I may mention the case of a little girl who was brought to me from one of the New England States, suffering from a mild type of epilepsy. I ordered a grain of the bromide of zinc three times a day, and a diet consisting exclusively of skimmed milk, with instructions for the parents to bring the child back again at the end of a month. The child's condition began to grow worse immediately after the commencement of this treatment, but, instead of letting me know about it, the parents observed my directions literally until the end of the month, and then brought the child back again suffering from as many as three hundred epileptic paroxysms daily. The paroxysms followed one another in rapid succession. I saw at once that the restricted diet had produced anæmia of the brain, and thus had aggravated the child's condition rather than improved it. The diet was changed, she was given beefsteak and other nourishing food, and within three days the paroxysms were reduced to one in twenty-four hours.

This child has never taken any medicine. It is not often that we meet with a case of epilepsy in which the bromides have not been tried, and tried very properly, too. Of course, we can not consider the pathology of the affection on this occasion. There are a good many different kinds of treatment which have been resorted to within recent years which are of considerable importance. Whenever a patient has an aura, as this child has, you may do a

great deal of good by giving something which will prevent the development of the paroxysm. It is a remarkable fact that epileptic attacks may be kept up by the force of habit, even after the original cause has been removed. For instance, a child may swallow an apple-core, and that night have an epileptic fit. Now, although you may get rid of the apple-core by the administration of a purgative, another fit may occur within a short time merely from the force of habit, which has been so readily established. I know of no other disease which becomes habitual so readily as does epilepsy. Hence, the first thing to be done in all cases of epilepsy is to break up the habit. There are two important ways of doing this: first, when the patient feels an aura, if three or four drops of the nitrite of amyl be put upon a handkerchief and inhaled, the paroxysm will almost certainly be aborted. I have cured several cases of epilepsy by that method alone, without the administration of any internal remedy. The drug should be put to the mouth so that it may be inhaled thoroughly. When inhaled thoroughly in this way, it will produce a sensation of fullness in the head, a tingling of the surface of the body, and redness of the face. Nitro-glycerin, or glonoin, may be used for the same purpose. It takes a longer time to act, but its effect is more permanent. Nitrite of amyl will prevent a paroxysm, but it is liable to come on within an hour or a short time afterward. The strength required is one drop of glonoin to one hundred of alcohol, and it may be administered in pill form, the best preparation being that of Metcalf, of Boston. Two drops of the one-per-cent. solution may be given to an adult. It produces a feeling of fullness in the head, a slight pulsating headache, with acceleration of the pulse. The drug may also be given on a little sugar. Nitro-glycerin is one of the remedies used also for the permanent treatment of the disease. In epilepsy there is at first a general anæmia of the brain; so long as this organ is in a hyperæmic condition it is impossible for a paroxysm to occur. It is on the principle of producing a hyperæmic condition of the brain that the nitrite of amyl and nitro-glycerin abort the epileptic attack. The same result may be obtained by putting an elastic band around the neck, preventing free venous return, and causing a fullness of the cerebral blood-vessels. I know of two cases of epilepsy which were cured in that way. In another case the patient applied the band at the time she felt the aura, and it prevented the paroxysm; afterward she wore it constantly, and had had but three attacks within about four months, whereas previously she had been having as many attacks in twenty-four hours. Now, curiously enough, Dr. Corning proposes to treat epilepsy by compression of the carotid arteries, and doubtless he has obtained marked results in some cases by the use of an instrument which he has invented for this purpose. But you know that it is almost impossible to compress the carotid artery with any instrument without at the same time compressing the jugular vein, and I am of opinion that this is the true explanation of the beneficial results which he has obtained.

For a permanent cure of a case like the present one, I think it is always best to begin with the administration of the bromides in some form or other. There is no use in

trying the old remedies, such as the nitrate of silver, the sulphate of copper, the salts of zinc, etc. Some of the salts of zinc, however, are sometimes beneficial, but they are more efficacious in conjunction with the bromides than when administered alone. But, in general, to use those old remedies will be to throw precious time away, for they will not reduce the frequency of the paroxysms oftener than in one case in one or two hundred, whereas the bromides will do so almost invariably, and, if the case be not an old one, they may effect a permanent cure. I usually begin the treatment in the adult with a mixture consisting of four ounces of the bromide of sodium to a pint of water, a teaspoonful, which contains fifteen grains of the bromide, to be taken three times a day. The efficacy of the solution will be increased by adding half an ounce of the iodide of potassium. It will take several days for the drug to produce any effect, for it acts slowly. When a physician tells me he has induced sleep in a patient by a single ordinary dose of the bromide of potassium I do not believe it; it requires more than one dose of fifteen grains several times daily, given for from two to four days, to produce any decided effect. Perhaps a single dose of a hundred grains would put the patient to sleep, but it is not usually administered in such large quantities. A teaspoonful of the mixture should be given largely diluted with water, for the effect of these salts is greatly increased when they are largely diluted with water. I increase the dose one fourth every three months for a year, and continue it at that for another year. It is then reduced in the same manner, and during the fourth year the patient takes fifteen grains of the bromide three times a day. If the quantity is not increased during the first year, the attacks will probably recur, and you will then find it very difficult indeed to check them. I used to teach that it was not necessary to give the bromide longer than two years, but I found afterward that in a few cases there was a relapse, and it is safer, therefore, to continue the treatment for four years. Indeed, if I were subject to epilepsy myself I should continue to take the bromides all my life, thus avoiding any probability of a recurrence of the paroxysms. If after a time the bromide treatment does not produce as marked results as are desired, I would advise you to stop for a month, or longer, until the system has had time to become perfectly free from the drug, and then begin the treatment anew. In the mean time something should be given to quiet nervous irritability, such as cod-liver oil and tonics. The patient must remember this fact, however, that unless a certain degree of bromism is produced the disease can not be cured.

The bromide treatment is not altogether unattended by danger. I have lost three cases from it. In one case, the patient lived in North Carolina, and wrote to me, complaining of the ill effects of the drug. Patients, however, are likely to magnify their troubles, and I replied that she had better see her local physician and follow his advice. She did so, but her physician did not like to take the responsibility of stopping the treatment, and it was continued. She died shortly afterward from bromism. In another case, that of a young lady, pneumonia supervened on bromide poisoning and caused death. I have observed that bromism

predisposes to lung trouble. In a third case a young lady disobeyed my instructions and exposed herself, took pneumonia, and died. If, however, your cases are under your own immediate supervision you can watch them, and, when the effects of the drug are becoming too marked, decrease the dose, and it will not be likely to produce any serious result. It is necessary to affect the constitution pretty strongly, else a cure can not be obtained. Weakness short of ability to stand up, and an acne eruption on the face and chest, are not contra-indications to a continuance of the treatment. But I have had to stop the bromide frequently on account of indolent ulcers which it had produced. These can usually be cured easily by galvanism.

Another useful measure in the treatment of epilepsy is counter-irritation applied to the back of the neck by the platinum disc, or other instrument heated to a white heat. It is necessary only just to touch the skin, and then remove the cautery immediately. The pain produced is so slight that the patient scarcely feels it. I have known the number of paroxysms to be reduced after a single application of the cautery.

Gentlemen, I have only given you the important points in the treatment of epilepsy; it is impossible to treat the subject exhaustively in a single lecture.

MEDICAL ETHICS AND ETIQUETTE.

COMMENTARIES ON THE NATIONAL CODE OF ETHICS.

By AUSTIN FLINT, M. D.

Third Article.

THE DUTIES OF PHYSICIANS TO THEIR PATIENTS AND THE OBLIGATIONS OF PATIENTS TO THEIR PHYSICIANS.

(Continued.)

SECTION 3. Frequent visits to the sick are in general requisite, since they enable the physician to arrive at a more perfect knowledge of the disease—to meet promptly every change which may occur, and also tend to preserve the confidence of the patient. But unnecessary visits are to be avoided, as they give useless anxiety to the patient, tend to diminish the authority of the physician, and render him liable to be suspected of interested motives.

It is generally left to the physician to judge of the frequency of visits which cases require. He is asked by patients, or their friends, much oftener to increase than to diminish the number of his visits. Not infrequently he is asked to make the number greater than, in his judgment, the case requires. Patients who are able and willing to incur the expense of superfluous visits are entitled to them, if professional attendance necessary in other cases be not thereby prevented. But it is fair, both to the physician and patient, to state that a certain proportion of visits made at the request of the latter are not required by the circumstances of the case. In this way useless anxiety on the part of the patient from unnecessary visits is avoided.

Physicians, naturally, are sensitive respecting an imputation of making more visits than cases require, and, for this reason, they may make fewer than are advisable. Young practitioners, who are known to be struggling for a livelihood, are especially apt to be sensitive on this point. Owing to the infrequency of visits in consequence of this sensitiveness, they may appear not to be sufficiently interested in a case, or not to attach to it sufficient importance. It is always better to make too many than too few visits. The former error is easily corrected, but the latter does not admit of correction. The instances must be extremely rare in which physicians multiply visits beyond the requirements of a case for the purpose of pecuniary gain. Instances are much more frequent in which they fail to do justice, both to their patients and themselves, in this regard.

SECTION 4. A physician should not be forward to make gloomy prognostications, because they savor of empiricism, by magnifying the importance of his services in the treatment or cure of the disease. But he should not fail, on proper occasions, to give to the friends of the patient timely notice of danger when it really occurs; and even to the patient himself, if absolutely necessary. This office, however, is so peculiarly alarming when executed by him that it ought to be declined whenever it can be assigned to any other person of sufficient judgment and delicacy. For the physician should be the minister of hope and comfort to the sick; that, by such cordials to the drooping spirit, he may smooth the bed of death, revive expiring life, and counteract the depressing influence of those maladies which often disturb the tranquillity of the most resigned in their last moments. The life of a sick person can be shortened not only by the acts, but also by the words or the manner of a physician. It is, therefore, a sacred duty to guard himself carefully in this respect, and to avoid all things which have a tendency to discourage the patient and to depress his spirits.

It is a mild expression to say that gloomy prognostications made in order to magnify the importance of medical services savor of empiricism. Whenever made with that intent, they denote nothing less than downright charlatanism. The facility with which patients are led to an exaggerated estimate of medical services, and the disposition often, of their own accord, toward such an estimate, offer, in many instances, a strong temptation. Physicians not over scrupulous as to the means of obtaining a popular reputation for professional skill are likely to yield to the temptation. A well-educated physician must know that he can rarely assume to have warded off an impending disease. The statement to a patient that he has barely escaped an attack of pneumonia, typhoid fever, apoplexy, or other diseases which might be included in this category, is either evidence of ignorance on the part of the physician who makes the statement, or it is a gross violation of medical ethics. It is a popular error that most diseases can be foreseen by skilled observers, and prevented by skillful measures. The truth is, this can properly be said of but few diseases. The public are also equally in error in regard to the management of diseases. Certain diseases are controllable by known therapeutical agencies. Many, however, in the present state of our knowledge, can not be controlled; that is, arrested and brought at once, or speedily, to a favorable termination. In a considerable proportion the tendency is to end favorably.

bly, and this tendency might suffice, irrespective of any active treatment. The management of the diseases which are not controllable consists in close observation and watching for complications or untoward events, meeting indications as they arise in particular cases, palliating symptoms, relieving pain or distress, and sustaining the powers of life, thus endeavoring to promote a favorable termination, to diminish suffering, and, perhaps, shorten the duration of the disease.

It is, of course, dishonest, and, therefore, a violation of medical ethics, for a physician to claim more credit than that to which he is entitled in controlling diseases or in their management. A better understanding than now generally exists in the popular mind of the nature and scope of the offices of the physician, in these regards, will tend to place the medical profession in a better light before the public.

Forwardness in gloomy prognostications is not always evidence of a desire to magnify the importance of medical services. It may proceed from a mental tendency thereto. Some minds are so constituted that there is a constant disposition to look on the dark side and anticipate the worst. This is a misfortune in the practice of medicine, alike for the physician and his patients. The physician loses a potential factor in the management of diseases, and the patient suffers a corresponding disadvantage. Some physicians are over-sanguine in prognosis, and fail to appreciate fully the condition of patients in respect of danger. A *just milieu* is desirable; but, if there must be error in either direction, it is far better to err by looking on the bright side.

Undue solemnity, anxiety, and apprehension in the looks, manner, or words of a medical attendant on the sick, are extremely unfortunate—they discourage patients, whereas, on the other hand, a cheerful mien, calmness of deportment, and verbal assurances, sometimes accomplish more than drugs. Patients often declare that they are conscious of deriving benefit from the visits of a physician irrespective of his prescriptions, but the manifest effect is sometimes quite the reverse. It is a duty always to encourage patients as much as the circumstances of the case will allow. The encouraging features of a malady should be dwelt upon, and not those of an opposite character. Unfavorable events which may be apprehended should not be referred to in the hearing of the patient, although it may be judicious to mention them to friends, in order that they be not taken by surprise, and attach blame to the physician for concealment.

Patients, when seriously ill, do not often ask for explicit information as to the existence or the degree of danger. If the question be asked, it must, of course, be answered. The answer, with rare exceptions, should be so worded as not to exclude hope, but without deceiving the patient by holding out false assurances of recovery. To tell a patient that within a fixed period death is certain is not only a brutal violation of propriety, but such a belief is seldom warranted by actual knowledge. The writer of these commentaries has in several instances sat by the bedside awaiting the last breath in cases which have ended in recovery.

It may be a duty for the physician, of his own accord, to intimate, or cause to be intimated, to the patient that the disease is not without danger. It seems hardly right that persons should die from disease without having had any suspicion of danger; but this not infrequently happens. There may be important matters to be attended to in preparation for death. Last wishes and words are often of great comfort to surviving relatives and friends. As stated in the code, it is more appropriate for communications having reference to danger and death to be made by some one other than the medical attendant; but often others shrink from this painful duty, and, moreover, many are not competent to perform the duty with judgment and delicacy; hence, it falls upon the physician, and, under those circumstances, he should not decline it.

SECTION 5. A physician ought not to abandon a patient because the case is deemed incurable, for his attendance may continue to be highly useful to the patient, and comforting to the relatives around him, even in the last period of a fatal malady, by alleviating pain and other symptoms, and by soothing mental anguish. To decline attendance under such circumstances would be sacrificing to fanciful delicacy and mistaken liberality that moral duty which is independent of and far superior to all pecuniary consideration.

Instances are not extremely rare in which recovery from disease takes place when there had seemed to be little or no ground for hope. This fact renders it injudicious for the physician to pronounce a positively fatal prognosis even in cases which are apparently hopeless. There is no need of saying that death is certain, inasmuch as the statement of extreme danger answers every purpose as regards duty toward the relatives or friends, and, also, the patient. The physician should avoid committing his own mind to a fatal prognosis whenever there is the slightest foundation for hope, because the effect will be relaxation of his medical efforts. The effect of an abandonment of all hope on the minds of nurses, relatives, and friends, is bad. Their co-operative efforts are thereby relaxed, and not infrequently, as a desperate alternative, the patient is given over to experimentation with some irregular methods of practice.

It is trying to a physician to continue to visit patients when he feels that the resources of medicine are powerless, and to witness the closing scenes of life. But there is room for his good offices under those circumstances, and he should not withhold them. He can often do much toward lessening pain or discomfort—mental and physical; he can contribute to euthanasia, and he can comfort those who surround the bed of death by assurances that in the "last agony," as it is miscalled, these manifestations of distress are usually unattended by conscious suffering.

SECTION 6. Consultations should be procured in difficult or protracted cases, as they give rise to confidence, energy, and more enlarged views in practice.

Errorneous views respecting consultations prevail largely in the public mind, and, to a considerable extent, among members of the medical profession. A request for a consultation is often considered as implying lack of confidence in the attending physician. It is not an uncommon notion that the function of a consulting physician is to judge con-

cerning the practice which has been pursued, and announce his decision to the patient and friends. Some persons have the idea that the physician in consultation assumes entire control of the case, and that he is entitled to whatever credit may pertain to the management. It is not to be wondered at that, recognizing and perhaps sharing in these erroneous popular views, practitioners are anxious to dispense with consultations, if they can be avoided, and consent with reluctance when they are proposed. It is highly important that the public should have correct views of the proper objects of consultations. These objects are: co-operation in the management of cases of disease, a division of responsibility, and the satisfaction of patients and those interested, by enabling them to feel that, whatever may be the result, they have done all that lies in their power to secure the best resources of medicine. A medical consultation should not necessarily imply that the consulting physician has more knowledge and skill than the physician in attendance. The advantage is in having two or more heads instead of one head. Life and health are certainly of sufficient importance to claim the judgment of more than one person. Questions in law, or of the affairs of business, or of comparatively unimportant matters relating to rules of conduct, are often deemed of sufficient consequence to obtain collective opinions. How inconsistent, therefore, to rely upon a single mind in cases of disease which may lead, if not to death, to a permanent impairment of the mental or physical powers! Consultations, when their true objects are recognized by all parties, are of great comfort to an attending physician. Undoubtedly, a reason for their being distasteful to him often is a want of full confidence in the honor of the consulting physician. Hence, it is important that physicians comply conscientiously with the rules laid down by the code in respect of consultations. These rules will be considered under another heading.

SECTION 7. The opportunity which a physician not unfrequently enjoys of promoting and strengthening the good resolutions of his patients, suffering under the consequences of vicious conduct, ought never to be neglected. His counsels, or even remonstrances, will give satisfaction, not offense, if they be proffered with politeness, and evince a genuine love of virtue, accompanied by a sincere interest in the welfare of the person to whom they are addressed.

Members of the medical profession, as such, are not called upon to be expounders of doctrines of morals, still less partisans of any particular form of religious faith. The tendency of that knowledge of human character which is incident to the practice of their profession is to make physicians charitable, and tolerant of diversities of opinion in relation to ethics and religion. Seeing, as they can not fail to do, all that lies beneath the surface in the different stations and varied conditions of human life, they know that the worst traits of character may be found in the highest, and the best in the lowest, of the conventional grades of society. Owing to the intimate and unreserved relations of the physician to his patients, he can often do much toward carrying out the injunctions of that portion of the code which is prefixed to these remarks. It is undoubtedly true that persons will often listen more considerately to counsels

or remonstrances from a medical adviser than to those of relatives, friends, and neighbors, or even to the admonitions of the clergy. It is, perhaps, true that most persons are influenced more by considerations which have reference to life and health than to those which appeal directly to the moral nature. The evils resulting from the abuse of alcohol, the dangers connected with the habitual use of opium, chloral, and other drugs, and the consequences of licentiousness, may, in not a few instances, be pointed out more effectively by a physician who has the confidence of his patients than by any one else. It is clearly his duty not to forego any opportunity of "promoting and strengthening the good resolutions of his patients."

ART. II.—*Obligations of Patients to their Physicians.*

There are several reasons why this portion of the code calls for but little in the way of commentary. In the first place, the commentator being a member of the medical profession, it is a matter of delicacy not to dilate too largely on the obligations of patients to their physicians. In the second place, although in the preparation of these articles the hope is entertained that they will have interest for non-medical readers, there is probably little ground for the expectation that they will have an extensive popular circulation. In the third place, a large proportion of patients are fully sensible of their obligations to their physicians; and, lastly, the portion of the code which defines the obligations of patients to their physicians is so clear and comprehensive as not to offer much scope for addition or elucidation. For these reasons, instead of making each subdivision a separate heading for comments, the entire article will be first given, and, afterward, brief remarks on the topics which it embraces, following the order in which they are presented in the code.

SECTION 1. The members of the medical profession, upon whom is enjoined the performance of so many important and arduous duties toward the community, and who are required to make so many sacrifices of comfort, ease, and health for the welfare of those who avail themselves of their services, certainly have a right to expect and require that their patients should entertain a just sense of the duties which they owe to their medical attendants.

SECTION 2. The first duty of a patient is to select as his medical adviser one who has received a regular professional education. In no trade or occupation do mankind rely on the skill of an untaught artist; and in medicine, confessedly the most difficult and intricate of the sciences, the world ought not to suppose that knowledge is intuitive.

SECTION 3. Patients should prefer a physician whose habits of life are regular, and who is not devoted to company, pleasure, or to any pursuit incompatible with his professional obligations. A patient should, also, confide the care of himself and family, as much as possible, to one physician; for a medical man who has become acquainted with the peculiarities of constitution, habits, and predispositions of those he attends, is more likely to be successful in his treatment than one who does not possess that knowledge.

A patient who has thus selected his physician should always apply for advice in what may appear to him trivial cases, for the most fatal results often supervene on the slightest accidents. It is of still more importance that he should apply for assistance in

the forming stage of violent diseases; it is to a neglect of this precept that medicine owes much of the uncertainty and imperfection with which it has been reproached.

SECTION 4. Patients should faithfully and unreservedly communicate to their physician the supposed cause of their disease. This is the more important, as many diseases of a mental origin simulate those depending on external causes, and yet are only to be cured by ministering to the mind diseased. A patient should never be afraid of thus making his physician his friend and adviser; he should always bear in mind that a medical man is under the strongest obligations of secrecy. Even the female sex should never allow feelings of shame or delicacy to prevent their disclosing the seat, symptoms, and causes of complaints peculiar to them. However commendable a modest reserve may be in the common occurrences of life, its strict observance in medicine is often attended with the most serious consequences, and a patient may sink under a painful and loathsome disease which might have been readily prevented had timely intimation been given to the physician.

SECTION 5. A patient should never weary his physician with a tedious detail of events or matters not appertaining to his disease. Even as relates to his actual symptoms, he will convey much more real information by giving clear answers to interrogatories than by the most minute account of his own framing. Neither should he obtrude upon his physician the details of his business nor the history of his family concerns.

SECTION 6. The obedience of a patient to the prescriptions of his physician should be prompt and implicit. He should never permit his own crude opinions as to their fitness to influence his attention to them. A failure in one particular may render an otherwise judicious treatment dangerous, and even fatal. This remark is equally applicable to diet, drink, and exercise. As patients become convalescent, they are very apt to suppose that the rules prescribed for them may be disregarded, and the consequence, but too often, is a relapse. Patients should never allow themselves to be persuaded to take any medicine whatever that may be recommended to them by the self-constituted doctors and doctresses who are so frequently met with, and who pretend to possess infallible remedies for the cure of every disease. However simple some of their prescriptions may appear to be, it often happens that they are productive of much mischief, and in all cases they are injurious, by contravening the plan of treatment adopted by the physician.

SECTION 7. A patient should, if possible, avoid even the friendly visits of a physician who is not attending him; and, when he does receive them, he should never converse on the subject of his disease, as an observation may be made, without any intention of interference, which may destroy his confidence in the course he is pursuing, and induce him to neglect the directions prescribed to him. A patient should never send for a consulting physician without the express consent of his own medical attendant. It is of great importance that physicians should act in concert; for, although their modes of treatment may be attended with equal success when employed singly, yet conjointly they are very likely to be productive of disastrous results.

SECTION 8. When a patient wishes to dismiss his physician, justice and common courtesy require that he should declare his reasons for so doing.

SECTION 9. Patients should always, when practicable, send for their physician in the morning, before his usual hour of going out; for, by being early aware of the visits he has to pay during the day, the physician is able to apportion his time in such a manner as to prevent an interference of engagements. Patients should also avoid calling on their medical adviser unnecessarily during the hours devoted to meals or sleep. They should always be in readiness to receive the visits of their physician, as the

detention of a few minutes is often of serious inconvenience to him.

SECTION 10. A patient should, after his recovery, entertain a just and enduring sense of the value of the services rendered him by his physician; for those are of such a character that no mere pecuniary acknowledgment can repay or cancel them.

The demands for medical services are so irregular, occurring at all times of both day and night, that a physician in full practice can not systematize his work. He must often forego periods of study, sleep, and needed rest, meals at stated times, social enjoyments, and recreation. The demands frequently can not be deferred, and the services perhaps can not be performed by a substitute, even if one be available. These are not trifling hardships, but of greater weight are the peculiar anxieties and responsibilities pertaining to the practice of medicine. The pressure of these is felt as a heavy burden by most physicians, although it may be concealed by calmness, cheerfulness, and either brusque or jovial manners.

Notwithstanding its arduous duties and the many sacrifices which it involves, the medical profession does not lack members, and in many places it is overcrowded. There are but few communities in which patients have not a choice among a considerable number of practitioners. In selecting a medical adviser or a family physician, most patients are influenced not a little by external appearances and by feelings of friendly interest. It can not be expected that they can judge critically of professional attainments. To form any accurate judgment of skill in therapeutics is by no means always easy for the medical observer, and it is simply impossible for those who are not versed in medical knowledge to decide how much to attribute to nature and how much to art in recovery from disease. True it is that very many believe themselves fully warranted in assuming to determine in individual cases whether a practitioner deserves credit or blame; but this belief is no evidence of the correctness of the assumption. Many do not hesitate to decide as to the relative merits of what is known as the regular practice and the various systems which appeal to popular favor on the ground of having originated in advanced views of medicine. This fact is proof of credulity in matters pertaining to the practice of medicine; for surely no one can claim that the decisions often so readily formed have any logical foundation. Undoubtedly a pleasing address, together with good judgment and tact in matters not strictly connected with medical science, often goes far toward obtaining and preserving the confidence of patients. There is nothing wrong in this; but it need not be argued that to deserve confidence something more than these recommendations is requisite. It follows from what has been stated that the evidence of having received a good medical education is not to be overlooked in selecting a medical adviser. Of this evidence every one can form an opinion. Aside from official testimony, the good sense which a physician shows in matters not connected with medicine is to be taken into account, and the esteem in which he is held by his professional brethren. The importance of a discrimination among physicians according to their educational recommendations does not relate exclusively to the interests of

patients in selecting medical advisers. Such a discrimination is likely to have not an inconsiderable influence on the promotion of medical education.

Intemperance is a calamity as great in the practice of medicine as in any other calling. There are few spectacles more painful than a drunken doctor at the bedside of a patient affected with a disease involving immediate danger to life. Such a spectacle happily is rare. It can not be said that intemperance is largely prevalent in the medical profession. There is no need of impressing upon patients the fact that a physician devoted to drinking-saloons, the billiard-table, horse-racing, and other kindred pleasures so called, or to the gayeties of fashionable life, is not to be preferred to one of different habits and tastes. This is well enough understood. The acquaintances which a doctor makes in frivolous or low associations do not prefer him as their medical adviser. In like manner the public is sufficiently alive to the damaging effect on the professional character of the medical practitioner by an unduly absorbing interest in art, literature, or pursuits of any kind which, although in themselves worthy, direct the attention from the duties of his profession.

It is wise to select a medical adviser when in health. No one should be uncertain upon whom to call for professional services. The selection, if deferred in case of illness until a time when these services are needed, perhaps suddenly, can not be deliberate, and must often be determined by accident. A patient under those circumstances is liable to be placed in a situation of much embarrassment; the physician accidentally in charge may not prove acceptable, but it is painful to make a change. The responsibility in cases of disease should be concentrated upon one person. It is unwise to have several medical advisers—one for diseases of the chest, another for nervous diseases, etc. The interests of patients are best subserved by having those who are distinguished as specialists always act in concert with the one who stands in the relation of medical adviser. It is the duty of the latter to decide whether certain ailments are trivial, or whether they betoken an important malady; hence, the importance of consulting him at once, wherever there are any symptoms of disease. Patients who have a proper degree of confidence in their physicians will be unreserved in their communications, thus giving every opportunity of judging respecting the agencies which may be involved in producing or maintaining the conditions of disease. A physician never considers anything to savor of indelicacy which may have a bearing on the knowledge of the case which he is called upon to treat. On the other hand, the patience of physicians is sometimes sadly tried by needless details. After a brief account, a competent physician understands vastly better than the patient the different directions in which it is desirable to push inquiries. Lengthened descriptions of morbid sensations or feelings are not only needless and tiresome, but confusing. Above all, patients should forbear writing out a full history of their subjective symptoms.

There is a class of patients much dreaded by physicians, namely, those who insist upon being taken into a medical consultation with regard to the treatment. Such patients

desire not only to know what medicines are prescribed, but to discuss the reasons therefor; they are not content without exercising their own judgment concerning therapeutic indications and the means of fulfilling them. Still more, they sometimes undertake to dispense with or to modify the directions of the physician in his absence, according to their own ideas or modes of reasoning. It is not only very unsatisfactory to treat such patients, but they are likely to fail to receive the full benefit of judicious treatment. If a patient has full confidence in his physician, he should follow strictly, without contention or distrust, all medical directions. If a patient has not full confidence in his physician, it is best for all concerned that another be substituted.

The impropriety of professional conversations with physicians not in charge of a case should be understood by patients as well as physicians. A proper sense of propriety will deter the latter from making any inquiries as to the symptoms and treatment, or offering any observations. To act according to the advice of different physicians, the latter being in ignorance of the fact, is not only dishonorable, but prejudicial to the welfare of the patient. If the advice of more than one be desired, the proper way to obtain it is by a professional consultation, which no physician should ever decline, provided the one proposed to be called in consultation be acceptable to him. To request the services of a consulting physician without the knowledge and consent of the physician in charge is a gross discourtesy, and, if done under circumstances which imply lack of confidence, the latter is fully justified in relinquishing the case.

Patients who have lost confidence in their physicians should request discontinuance of their services. So essential is full confidence in the treatment of cases of disease that it is a false delicacy to conceal the want of it. It is best for both the patient and the physician that there be a change. The code states that common courtesy and justice require that, when a physician is dismissed, the reasons should be disclosed. But the loss of confidence is in itself a sufficient reason, no matter how unreasonable the loss may be. A high-minded physician can not wish to continue in charge if he can not have the confidence of the patient. He should take the initiative in the relinquishment of the case whenever he is satisfied that confidence is lost. The reasons for the loss of confidence in some instances may be as indefinite as in the following familiar lines:

"I do not like thee, Dr. Fell;
The reason why I can not tell;
But this I know, and that full well,
I do not like thee, Dr. Fell."

Now, under such circumstances, Dr. Fell should be satisfied with the information conveyed by these lines, and retire from the case.

The inability to systematize his work is a great drawback to the comfort of the medical practitioner. Patients can do not a little toward relief in this regard by observing the injunctions contained in the ninth section of the article of the code now commented upon. This reference suffices for that section. The tenth and last section of the article expresses a truth which, for the majority of patients, need

not have been expressed. The feelings of a patient at the time of recovery from disease, as contrasted with those at a later period, have furnished a subject for jests and humorous illustrations; but "a just and enduring sense of the value of the services rendered him by his physician" is felt by the patient as a rule, and the degree of grateful appreciation of these services by the many more than compensates for a lack of this appreciation by the few.

ON DR. SQUIBB'S RESOLUTIONS TO ABOLISH THE CODE OF ETHICS OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK.*

By C. R. AGNEW, M. D.

IF I understand the question before us, it is whether we shall report for or against Dr. Squibb's resolutions, a question substantially presented, also, in the resolution of Dr. Gouley, "that when the committee rises it shall report in favor of repealing the new code enacted by this society in 1882."

I rise to oppose these resolutions and all similar ones, and to urge that, when the Committee of the Whole rises to report to the society, its report shall be against the repeal of the existing code.

A year ago, after mature deliberation and a free discussion, this society, by more than a two-thirds vote, and in the exercise of its indisputable right, amended its by-laws so as to make them consistent with the laws of the State and public policy. It is true that various attempts have been made to promulgate the error that said action was hasty, imperfectly considered, and that a few "ambitious," "mercenary," and, not to say, unscrupulous members of the society, had brought it about; that "specialists" had been accomplishing their nefarious purposes through the force of ill-timed and badly directed energy. Such gratuitous allegations, however, have not stood for a moment the crucial tests of legitimate criticism or investigation, and may, therefore, be dismissed as unworthy of even this brief animadversion, much less the serious consideration of the medical profession of the country. In view of them, one has only to recall a little history, and to draw comfort from its evidences of the triumph, even though it be sometimes slow, of liberty of conscience over prejudice, misrepresentation, and intolerance. Revisers, all down the pages of history, have had to endure hardship, and the only way for those who are called upon to do the work of revising is to live above the low level of the fear of their fellow-men, and not to be confused, diverted, or intimidated, even though the torch of persecution be brandished in their faces by those who assume to be the moral lights of the world, and the appointed guardians of its best interests.

"Zeal to promote the common good, whether it be by devising anything ourselves or revising that which hath been labored by others, deserveth certainly much respect

and esteem, but yet findeth but cold entertainment in the world. It is welcomed with suspicion instead of love, and with emulation instead of thanks; and, if there be any hole left for cavil to enter (and cavil, if it do not find a hole, will make it), it is sure to be misconstrued, and in danger to become condemned. This will easily be granted by as many as know history or have any experience. For, was there ever anything projected that savored in any way of newness or renewing, but the same endured many a storm of gainsaying and opposition"?

The revisers who unanimously reported the by-law, or code of 1882, framed it to be consistent with the statutes of the State, especially the law of 1880. This society adopted the code by a very large vote, without even a verbal amendment, after hours of animated discussion. Under this code, or by-law, the medical profession of the State has prospered for a year, and might have gone on doing so for years to come, if it had not been for an agitation fomented by parties living outside of the limits of the State, largely aided, and, no doubt, on conscientious grounds, by the mover of the resolutions published and widely circulated in the "Ephemeris." The legitimate course would have been, to move either to give up the charter of the society or to amend the State statute of 1880.

It may be well for us to consider for a moment our position as a society in relation to the State.

Whence do we get the right to be here in session? Indisputably through our charter from the State. No one but a legally qualified medical man has a right to be a member of this society. It is nothing to the point to say that the diploma, or certified right to practice, comes from a medical school, and not directly from the State. In this State the law undertakes to regulate, by charter or otherwise, the powers which confer the right to practice, and the method is easy by which you may hold all who attempt to practice within the limits of the State to a strict legal accountability. It is true that this statute of 1880 regulating the practice of medicine is not all that it should be. It is not perfect, nor are the men who acquire rights under it. But it will be amended just as soon as the members of the medical profession cease to legislate for themselves in prescriptive codes, and join other public-spirited citizens in inducing legislators to protect the people, as far as practicable, against medical incompetency. Whence do we, as a society, get the right to make medical codes and other by-laws? From the State through our charter. The New York State statute of 1880 says: "Section 5. The degree of Doctor of Medicine lawfully conferred by any incorporated medical college or university in this State shall entitle the person to practice physic and surgery within the State after the person to whom it is granted shall have complied with section two of this act." Section two, referred to, provides for registry in the County Clerk's office before commencing to practice, etc., etc. Section four provides for the indorsing of the diplomas of persons coming to the State to practice, from without the State, by an incorporated university, medical college, or medical school, etc., etc.

The revised statutes of New York especially provide that every corporation, as such, has power "to make by-

* Remarks made before the Medical Society of the State of New York, in Committee of the Whole, at its Annual Meeting, February 7, 1883.

laws not inconsistent with any existing law for the management of its property, *the regulation of its affairs*, etc., etc." And, in accordance with this provision of the statutes, the Medical Society of the State of New York has the right to make by-laws not inconsistent with the laws of the State. Kent says: "These corporate powers of legislation must be exercised reasonably, and in sound discretion, and strictly within the limits of the charter, and in perfect subordination to the constitution and general laws of the land and the rights dependent thereon." If you look at your charter you will find that whatever quality your by-laws, or codes, may have, they must, to be legal, and to have binding force upon your members, and punitive power, be "not inconsistent with the laws of the State."

Now, Mr. President, I put it to this society, Are we prepared, even under the leadership of the eminent members—I do not call them conspirators—who have been sowing seeds of discord all through the year in the profession and in this meeting, to array ourselves against the letter of the law and the policy of the State? Or, are we prepared to adopt the resolution to rise and report to the society to repeal the new code? Report to repeal the new code if you please. There is not much in the new code that I strongly desire to see retained. I am quite ready to abolish all but one or two clauses of it. I do wish, however, especially to see the clause retained which binds us all to acknowledge the public necessity for a "legally qualified practitioner." "Members of the Medical Society of the State of New York, and of medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine." It is permissive, not mandatory. I wish to see the profession united to contend for that, and to secure a higher and better standard of legal qualification.

Having a safe basis, and one on which legislators and the public are willing to aid us, we may as speedily as possible raise the standard of medical education, and express, in amendments to the laws regulating the practice of medicine, a higher and higher ideal, and force schools and legislators to apply higher standards of fitness for practice. What I am opposed to here is the declared or implied purpose of the movers of both resolutions, namely: to re-enact the old code, and to throw on the profession, powerless to do the work, what belongs to medical schools and legislators.

One great defect in that old code was, that it had come, in the process of time and growth of legislation, to be inconsistent with public policy in our State and with its statutes. Would it not be grossly opposed to public policy and the letter of the law of the State to attempt, by any code or by-law of our making, to strip a fellow-citizen of a right which the State had conferred upon him—a right identical with that in the exercise of which we are authorized to be here to-night as duly qualified medical men.*

The man whom the State has enfranchised this society can not disfranchise. The medical man whom the State has pronounced to be a legally qualified practitioner, this

chartered State Society can not disfranchise, however much we may despise him or refrain from social communion or fellowship with him. We can not discipline a member of our society if his conduct is in conformity with the law of the State.

Pass Dr. Squibb's or Dr. Gouley's resolutions, attempt by your vote to re-enact the old code, and you take action which will certainly be decided to be against public policy, and your action in making the by-law proposed is inconsistent with the laws of the State. I here quote from a paper by Professor D. R. Jaques, Professor of Municipal Law, University of New York.

"What is the code of ethics? What is the power of the State Society to enact one, or to legislate on any subject? What are the relations of the County Society to the State Society?"

"The State Society and each county society are *distinct corporations*, each with power to acquire and hold property, each with an organization of its own. The State Society is composed of certain permanent members, whom it selects in a certain proportion to the other members, and of members elected periodically. The act of 1813 speaks of them as members, not *delegates*. The State Society is not so much a representative body as a distinct and corporate board of control. The suggestion that the members elected by the county societies must vote as *instructed* by them is untenable. A doubtful principle in any case, it would convert the State Society into a *federal organization*, and would, in effect, require the members to vote *by counties*. In this way rules might be adopted which were disapproved of by a large majority of the practitioners of the whole State belonging to the county societies.

"Moreover, who, it may be asked, are to instruct the *permanent members*?"

"*Instruction* makes the delegate a mere messenger, to carry the conclusions of the county to the State Society. But the members of the State Society are corporators of a distinct body, and go to its meetings to form, receive, and adopt conclusions, as the result of views gathered from all sections.

"But the statutes are conclusive on this point.

"They require that in ALL cases the rules and regulations of the county medical societies shall receive the *sanction of the State medical societies*, and the act of 1866 (Chap. 445) applies this restriction to the homœopathic county societies as well. Now, if the county societies may instruct the members they send to the State Society, a majority of the counties could always control the State Society, which would be its mere creature and mouthpiece; whereas, the act of 1813 in terms declares that the 'by-laws, rules, and regulations' of the county societies shall not be 'repugnant' to those of the State Society.

"The rules of the Code of Ethics are *by-laws*. Their force and effect are the force and effect they have as *by-laws*. The authority to adopt the old rule and the new rule of consultations must be found in the power given by statute to adopt by-laws and rules. The act of 1813 and the act of 1866 are explicit in requiring that the by-laws, rules, and regulations of the State Society shall not be 'incon-

* See case of The State and relator Gray against Medical Society of the County of Erie, 24 Barbour.

sistent' with the *laws of the State*. There may be an '*inconsistency*' which is not a direct violation of the law; but it is believed that the old rule is contrary to both the spirit and letter of the law, as it is contrary to the dictates of a broad and true humanity and the interests of medical science.

"It is not consistent with the *letter* of the statutes which prescribe the qualifications of practitioners. It says in effect that the employment of physicians whom the law has sent into the community and pronounced qualified, thereby inducing the ignorant and the unwary to intrust them with their lives, shall be punished by deprivation of all benefit from the counsels of enlightened physicians. Will the law allow patients to be punished for employing those the law pronounces qualified?

"But there is another consideration, equally serious:

"The rule in question is the action of an organized body of men. It is the act of combination. The men thus combining are considered by many—and consider themselves—the most competent practitioners, the *only* fully qualified practitioners of the State. By adopting this rule, they *combine* to deprive the community of the best advice to be had in cases of sickness. Such a combination is against common law and the provisions of the statute as well (Penal Code, section 168). It is a conspiracy against the public health."

What are we to do then, Mr. President? For the present, keep the code as it is. After we shall have defeated the attempts in this society to lead us to rebel against public policy and the law of the State by re-enacting the old code, it will be time enough to say what we may do to amend the existing code. We shall be ready for that question in due season. We have not lowered our flag to any "ism," nor do we propose to.

"There is probably no one thing which man, considered collectively, grants less willingly to his fellow-man than liberty. Nine tenths of all the wars which have desolated the earth, and no small part of all the ills that have afflicted humanity since the race began, have been due to a denial on the one hand, and an attempt to gain possession on the other, of those attributes of freedom which modern thought is coming to regard as among the inborn, inherent, and inalienable rights of every individual. And still the struggle goes on. Liberty of the person, liberty of belief and worship, liberty of speech and press, and liberty to have a voice in the choice of rulers and forms of government"—I would also add liberty of medical consultations—"are still privileges denied to no small part of mankind; and any extension of liberty in these respects in the future, as in the past, will probably be conditioned upon long-continued, desperate efforts, and upon the payment in blood, treasure, and suffering of large price."—D. A. WELLS.

Charles O'Connor, the great jurist, in a recent letter to your speaker, says, the "general doctrine of emancipation from every unnecessary restraint upon individual liberty in action or pursuit, which forms the basis of the argument" (referring to the speaker's "Limits of Medical Ethics") "has long had me for a disciple."

After we shall have defeated the attempts to re-enact

the old code, let us return to our counties determined to carry into effect the laws we have against illegal practitioners, and to make the laws better. How many counties represented here have done their duty in this matter? New York County has endeavored strenuously to do its duty. Twenty-seven illegal practitioners have been arraigned in New York City during the past year, and twenty-five of the number have been convicted and punished. And at this moment charges are being pressed against a medical college there, with good prospect of convicting its managers of illegal methods of granting diplomas.

But the question is pertinent, What are we doing individually for higher medical education? How many public-spirited men have we attempted to enlist in the cause of medical education in our respective counties? How much have we done to advance the interests of our medical alma mater, to give it the means to make its diplomas more valuable? How much have we done individually to change the character of proprietary medical schools, and to secure for them adequate funds and a more thorough and severe curriculum?

When we shall have begun even to consider honestly these and kindred questions, we shall soon see the standard of medical education and of the legally qualified doctor rise, and the petty questions of schools and "isms" will, like other ephemeral issues, vanish or become despicable.

As regards error in medicine, what Thomas Jefferson said in another field is undisputably true here also: "Error of opinion ceases to be dangerous when reason is left to combat it." Leave members of a liberal profession free to go as advocates of the truth wherever called, and only restrained by the rules of common decency, legality, and prudence, and error will be less arrogant and dominant, and the dupes of error less numerous, or more quickly rescued.

INTRA-UTERINE INJECTIONS IN THE TREATMENT OF PUERPERAL SEPTICÆMIA.*

By T. GAILLARD THOMAS, M. D.

CLINICAL PROFESSOR OF GYNECOLOGY IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE following case seems to me to illustrate what should be the accepted treatment of puerperal fever, or puerperal septicæmia, at the present day. The case was that of a lady in the higher walks of life whom I was called to see about a month ago, in consultation by her physician, a man of wide experience. She was a primipara, was taken in labor at four o'clock Sunday afternoon, and at nine o'clock in the evening was delivered of a female child, without any difficulty or assistance. Her physician examined the external genitalia carefully, and found no tear whatever. The nurse was instructed to syringe out the vagina carefully the next day with carbolized water, which she did. The first forty-eight hours passed by without any bad symptoms at all, but, on visiting her on Tuesday morning, the physician found a temperature of 101° F., and in the evening it had

* An abstract of remarks made before the New York Medical and Surgical Society, February 10, 1883.

risen to 102.5°. The next morning, the morning of the fourth day, the temperature was 103°, and the patient began to complain of very severe pain in the right iliac fossa. There had been no chill. At five o'clock in the afternoon the temperature was 106.5° in the mouth. The patient's appearance became wild, as of one who was about to have puerperal mania; the skin was hot, and she was crying out with pain, although she had received a good deal of morphine.

Having now been called to see the patient, I took the temperature in the mouth myself, and confirmed the record of her physician, that it was 106.5°. The pulse was 145. Making a vaginal examination, I found a bilateral laceration of the cervix uteri extending nearly up to the vaginal junction. Probably this extensive laceration partly accounted for the rapidity and the ease of the labor as occurring in a primipara. I urged that the uterus should be washed out with carbolized water at once, but her physician had never seen the method practiced, and was strongly prejudiced against it; he finally consented only because it was apparent that unless something decided was done the patient would soon die. Using the Chamberlain tube and the Davidson syringe, Dr. Jones, and afterward Dr. McCosh, continued to wash out the uterus with carbolized water every four hours during the night, and the next morning the temperature was found to have sunk from 106.5° to 101°; the pulse had fallen from 145 to 120; the patient, who had been given opium quite freely during the night, declared that she was very much relieved. Indeed, the relief had been so extraordinary that they began to believe that the danger was not real at all; that some exceptional circumstance had occurred, and that there was no septicæmia. The uterus was now washed out at longer intervals, but at once the temperature went up to 102°, 103°, 104°, and 105°, and the patient again began to look maniacal. The uterus was now washed out every three hours, opium was freely administered, ten grains of quinine were administered every eight hours, ice-water was passed through a coil of rubber tubing placed over the abdomen; and as long as this treatment was kept up the temperature did not rise above 101° or 102°; but so soon as they ceased to wash out the uterus the temperature at once rose to 104°, and at times to 105°. This fact was proved by repeated trials.

After this treatment had been continued for ten days, a physician remaining with the patient day and night, giving the injections every three hours, and thirty grains of quinine during the course of the day, it was believed to be time to stop it; but in less than twenty-four hours the temperature again rose to 105°. I mention the amount of quinine which was being taken particularly, so as to prove positively that there was nothing of a malarial character in the case at all. On the sixteenth day after delivery, the tenth day after the commencement of the high temperature, the intervals between the uterine injections were extended from three hours to four, then to five, six, and seven hours, and finally they were discontinued altogether, and at the same time the administration of quinine was given up and the coiled tubing was taken off. Opium was continued in

small doses for a while longer, and the patient recovered entirely.

I wish to contrast this case with another which I saw just before—that of a woman who had been recently delivered of her third child. When I was called to see the patient the temperature was 106°; she had been taken with violent pain in one iliac fossa, and had been put five days before pretty profoundly under the influence of opium, and a blister had been applied over the whole of the abdomen. Large doses of quinine had likewise been administered. When I saw the patient the use of intra-uterine injections was begun at once, but the patient lived only twenty-four hours, and died in a state of coma.

It seems to me that the time has arrived when puerperal septicæmia should be treated upon just as simple a plan as septicæmia of any other kind is, namely, by washing with some antiseptic fluid the surface where the disease originates—some fluid which will remove the poisonous material which is being absorbed, and also, so far as possible, neutralize its poisonous qualities. In brief, I would say that puerperal septicæmia, with our present light on the subject, should be treated in the following manner: First, wash out the uterine cavity completely with some antiseptic fluid; second, quiet all pain by opium; third, get the peculiar influence of quinine upon the nervous system; and, fourth, keep the temperature, at all hazards, at or below 100° by the methods which we now possess. Three years ago, at the American Gynæcological Society, which met in Baltimore, I took the ground which I take to-day regarding this subject, and only one gentleman in the entire society supported my view. Every other member who spoke referred to the dangers of introducing air into the uterine sinuses during the injection, etc. But I believe that the dangers attending the use of the injections are counterbalanced by the benefits to be derived. I do not think there is the least probability that air will be introduced if a tube of large size—as large as the finger—is used. But when a catheter is employed there is some danger of inserting it into a sinus and introducing air and fluid together directly into the vessels.

GARTNER'S CANALS.

By HENRY J. GARRIGUES, M. D.

NEW YORK.

In this journal for March 17th I find an abstract from an article by Kocks, on "Gärtner's Canals," and extensive reference is made to a report submitted by me to the Obstetrical Society two years ago on a cyst which I supposed to be formed by one of these ducts ("N. Y. Med. Jour.," vol. xxxiv, p. 623). At that time I fell into the common error of spelling the name of the man who found these organs, Gaertner and Gärtner, and so he is called in the abstract referred to. The true spelling is, however, Gartner. The man's full name was Herman Treschow Gartner. He was born in 1785, on the island of Saint Thomas, graduated in Copenhagen in 1815, and obtained a silver medal from the Royal Danish Society of Sciences in 1822, for "An Anatomical Description of a Glandular Organ examined in the Uterus of some Species of Animals."

In the above-mentioned report I stated that the only point in the specimen examined which did not correspond with the structure of the *vas deferens*, which in the male is homologous with Gartner's duct in the female, was the character of the epithelium, which in the cyst was flat, and is described as columnar in the *vas deferens*. I had then not noticed that Kolliker, in his "Entwicklungsgeschichte," second edition, p. 981, states that in a female embryo of a calf he found Wolff's duct, which is the same as Gartner's duct in the adult animal, composed of a flat epithelium and a thin fibrous membrane. Thus the missing link in the chain of evidence connecting the cyst in the vagina examined with Gartner's duct is found.

Finally, I would state that the two tubes now described by Kocks, and looked upon as remnants of Gartner's ducts, were described by Dr. Skene, of Brooklyn, three years ago (see "Am. Jour. of Obst.," 1880, vol. xiii, p. 265, *et seq.*). This observer thinks, however, that the tubules terminate at their upper end in a number of divisions, which branch off into the muscular substance of the urethra. This ramification would contradict Kocks's theory that these ducts are the remnants of Gartner's canals; but since, on Dr. Skene's figure 5, these ramifications appear as very small openings in the wall of the comparatively large canal formed by the duct, it seems likely that these so-called branches are muciparous glands situated in the mucous membrane lining the ducts.

Book Notices.

Labor among Primitive Peoples: showing the Development of the Obstetric Science of To-day, from the Natural and Instinctive Customs of all Races, Civilized and Savage, Past and Present. By GEORGE J. ENGELMANN, A. M., M. D., Professor of Obstetrics in the Post-graduate School of the Missouri Medical College, etc. Fifty-six illustrations. St. Louis: J. H. Chambers & Co., 1882. Pp. xviii-203.

DR. ENGELMANN'S modest little volume is evidently the result of a good deal of painstaking investigation of the customs of various races, ancient and modern, with regard to the care of parturient women. The author mentions that his interest in the matter was first excited by the study of an ancient Peruvian burial urn bearing a sculptured representation of the process of delivery. His own travels, supplemented by investigations of ancient pottery and paintings, by correspondence with those who have been so situated as to be able to furnish information as to the procedures adopted among various primitive peoples of the present time, and by examination of the works of preceding writers on the subject, have enabled him to bring together a great mass of facts, illustrated by quite a number of pictorial representations, the latter being authentic and for the most part highly graphic, their quaint simplicity and avoidance of any attempt at the artistic being the best possible proof of their fidelity to the scenes they purport to show.

As regards all the obstetric manipulations now practiced among civilized peoples, save only those involving the introduction of instruments or the hand into the uterus, they find their counterparts, more or less rational and efficient, among the various savage tribes and uncivilized communities with which the book deals, whether resorted to from more instinct or in

conformity with some rough notion of the relations of cause and effect. Even manual expression of the placenta falls within this statement. Most space is devoted in the book to the various postures assumed during labor in the different countries referred to, and it is a matter of great interest to note the wide range covered by the postures described and figured, including almost every conceivable variety of the horizontal decubitus, reclining attitudes, squatting, sitting, kneeling, standing, hanging, etc., as well as the diverse manoeuvres resorted to by the assistants.

Such an inquiry as this can not fail to prove of great value to the student of obstetrics, and we think that Dr. Engelmann is very much to be commended for having taken so much pains with it. The volume may be read with advantage by every general practitioner, since it contains much from which he will be able to draw deductions applicable in daily practice. The mechanical get-up of the book is not altogether pleasing, for reasons sufficiently set forth by the author in his preface.

BOOKS AND PAMPHLETS RECEIVED

The Pathology and Treatment of Diseases of the Ovaries. (Being the Hastings Essay for 1873.) By Lawson Tait, F. R. C. S., Edinburgh and England, Surgeon to the Birmingham Hospital for Women, etc. Fourth edition, rewritten and greatly enlarged. New York: William Wood & Co., 1883. Pp. 357.

Diagnosis of Ovarian Cysts by Means of the Examination of their Contents. By Henry Jacques Garrigues, A. M., M. D., Obstetric Surgeon to the Maternity Hospital, etc. New York: William Wood & Co., 1882. Pp. iv-112.

The Untoward Effects of Drugs. A Pharmacological and Clinical Manual. By Dr. L. Lewin, Docent of Materia Medica, Hygiene, and Public Health in the University of Berlin. Second edition, revised and enlarged. Translated by J. J. Mulheron, M. D., Professor of Principles of Medicine, Materia Medica, and Therapeutics in the Michigan College of Medicine. The only English translation having the author's indorsement. Detroit: George S. Davis, 1883. Pp. 216-vi. [Price, \$2.25.]

A Medical Index, being a Completely Indexed Note Book for Students, and for Physicians a General Index and Record Book for all Valuable Professional Reading and Experience. Ann Arbor: Joel A. Miner. Pp. 19-380.

A New Index Rerum for Students and Professional Men. Arranged to Minimize the Labor of Indexing, and to Classify all Indexed Subjects. Ann Arbor: Joel A. Miner.

An Index of the Practice of Medicine. By Wesley M. Carpenter, M. D., Assistant Pathologist to Bellevue Hospital, etc. New York: William Wood & Co., 1883. Pp. 304. [Interleaved.—Pocket cover.]

Circular. War Department, Surgeon-General's Office, Washington, D. C., February 20, 1883.

Cottage Hospitals. By Lucius W. Baker, M. D., Physician in charge, Children's Hospital Cottages, Baldwinsville, Mass. Read before the Massachusetts Medical Society, June, 13, 1882. West Gardner, Mass., 1882. Pp. 10.

The Law of Human Increase. By Nathan Allen, M. D., LL. D. Pp. 10. [Reprint from the "Popular Science Monthly,"]

The Prevention of Insanity. By Nathan Allen, M. D., of Lowell. Boston, 1883. Pp. 23.

Suggestions regarding the Local Treatment of some of the Commoner Affections of the Ear. By Samuel Theobald, M. D., of Baltimore. Pp. 6. [Reprint from the "Maryland Medical Journal,"]

Jahresbericht des Verwaltungsrathes des deutschen Hospital- und Dispensary in der Stadt New York, für das Jahr 1882.

NEW YORK, SATURDAY, MARCH 31, 1883.

RESTRAINT AND SECLUSION IN LUNATIC ASYLUMS.

THAT the harsh, flippant, and for the most part undeserved criticism that has been so freely poured upon American superintendents of lunatic asylums of late years has not driven them into a stubborn spirit of defiance, but has rather been met by them with wholesome self-criticism, is a fact that redounds very much to their credit. At the same time, there has been no servile surrender, no sop thrown to sentimentality in the shape of cant. We have been very much pleased with the tone that has pervaded the recent reports of the medical officers of such institutions, particularly those of the Bloomingdale Asylum, in this city, and two of the Illinois asylums.

Dr. Charles H. Nichols, of Bloomingdale, expresses himself as in full accord with what may properly be called the American doctrine and practice, which is, as he understands it, that neither mechanical restraint nor seclusion should ever be resorted to unless, in the opinion of a competent and responsible medical officer, protection in particular cases against violence, exhaustive activity, the removal of surgical dressings, etc., can be effected more easily, completely, and beneficially to the patient than by either the hands of attendants, medicinal agents, showers and douches (which he considers inadmissible except in a very limited number of cases), or "packs," wet or dry, which are obviously a very positive form of mechanical restraint, though their therapeutical advantages may now and then be superior to any substitute for them; but that it is the duty of the practitioner to resort to mechanical restraint or seclusion whenever he clearly sees that it is needed upon the grounds stated. Of course, he continues, the actual practice in the use of restraint varies more or less in different institutions in this, as he believes it does, actually and necessarily, in every other enlightened country, and is governed, as other measures of treatment are, by the training and character of the medical officers in charge, the opinion and support of the trustees, the number and character of the patients with respect to the extent and quality of their accommodations, the proportion of attendants to patients, the scale of expenditure, and other agencies of treatment. The restraint needed in the same institution will vary greatly according to the varying conditions of patients. While entirely unwilling to be governed by a prohibitory dogma or an arbitrary proportion to patients in the use of restraint, he is of the opinion that the circumstances that justify its average use in more than two or three per cent. of the cases under treatment must be quite exceptional. Seconded by the present assistant physicians of the institution, who have been earnest and efficient in their co-operation, the effort was made last year

to see how far restraint, either by mechanical instrumentalities or seclusion, could be reduced without violating the principles laid down, and on the men's side of the house restraint with the camisole or the bed-strap, or by seclusion, was resorted to in the course of the year in only eleven different cases (once in three cases, three times in two cases, four times in two cases, five times in two cases, six times in one case, and seven times in one case, for periods varying from one to twelve hours). On the women's side of the house more restraint was used in the early part of the year, but in the last seven months it was used in only two cases, three times in one case, and four times in the other, for periods varying from one to ten hours. In the foregoing list of restraint used is included seclusion in three different cases of paroxysmal mania in men and one of general paralysis (four times in two cases, five times in one case, and once in one case, for periods varying from two to six hours). Seclusion was not resorted to in any other case, and the habit of voluntary seclusion into which certain old patients are inclined to fall has been entirely broken up. It is distinctly stated that the reduced use of restraint has not been attended by an increased use of nervous sedatives or hypnotics, which have, in fact, been very sparingly used. On the contrary, more dependence than ever before has been placed upon the composing and indirect hypnotic effects of tonic and stimulant treatment and the use of warm medicated baths and massage at bedtime.

Dr. R. S. Dewey, of the Illinois Eastern Hospital, at Kankakee, reporting on a period of two years, ending September 30, 1882, treats of various matters connected with the management of insane patients in a most interesting and painstaking manner. At present we can refer only to his remarks on the special subject under consideration. He states that the guiding principles in the employment of mechanical restraint and seclusion at the Eastern Hospital have been: First, that they were to be employed only directly and personally by the physician, he being present and judging for himself, in each instance, of the necessity, *before* the measure was taken; second, that skill was to be substituted, so far as possible, for force, and all other available resources were to be exhausted before calling in the unwelcome aid of mechanical appliances. The factor exercising the most influence in reducing the employment of mechanical restraint has been the keeping of all the means of restraint—the muffs, camisoles, etc.—under the physician's control in the dispensary, sending them to the wards only by specific direction of the physician, and for a certain definite time, after which they were to be returned from the ward. The amount of restraint has constantly diminished under the methods employed. The instances in which it has been used on each side, respectively, in the year ending September 30, 1882, have been ten times in all on the female side, and six in all in the male division.

Figures are given which show a steady decrease of restraint for the whole three years in which the hospital has been in operation; with advantage, Dr. Dewey thinks, to the patients themselves and to the general spirit and disposition of the attendants, who learn to depend more upon skill, watchfulness, and tact, in their intercourse with patients, and upon gaining

and keeping their good-will and confidence, than upon any external or mechanical appliances.

In the first year, in the male division, seclusion was employed in one hundred and twenty-one instances, and in the second year in seventy-six instances. The figures upon the female side for the two years were, respectively, one hundred and sixty-seven and three hundred, the seclusion during the second year being for proportionally much shorter periods than during the first year. Thirty-six male and thirty-nine female patients were the subjects of seclusion. On the female side, it was found that several patients were benefited, or a paroxysm of high maniacal excitement was avoided, by an occasional brief seclusion of an hour, or even less. The average duration of seclusion, in each instance, for the two years, was six hours and a half on the male side, and five hours and a third in the female division.

Mention is made of the use of the "crib," or covered bed, and "mittens," which are not included in the preceding remarks. On the male side of the house, during the two years, an average of 1.38 persons have occupied such a bed (nine hundred and twenty-eight nights and eighty-four days, with an average of 179.67 male patients). This use of the crib was by fifteen or twenty individuals, mostly paralytic or epileptic patients, inclined to fall out of an ordinary bed, or feeble subjects of melancholia, who would rest when kept in bed by this means and not otherwise, and who made scarcely any resistance to occupying the crib. The cribs are large and roomy. A patient can sit up in all of them nearly erect when the cover is down. They are not made specially strong, and are not intended or used for cases accompanied with acute maniacal disturbance. On the female side, the crib was used two hundred and eighty-three nights and eight days in the two years, with an average of 96.2 patients, and part of this was for surgical reasons. It is Dr. Dewey's belief that the crib bed has a certain limited but very useful purpose, in the securing of rest for certain classes of the insane.

The leathern mittens, applied to the hand and secured around the wrist, to prevent destruction of clothing, are by many, he remarks, not regarded as a means of restraint, since they do not in any way impede the movements of the limbs. They were used, to quite an extent, for male patients in the earlier part of the biennial period, and no record was kept of their use; but they were not used for male patients at all during the last eighteen months. On the female side, the mittens were used thirty-one times, for a total of two hundred and eight hours.

Dr. Wardner, of the Illinois Southern Hospital, at Anna, touches upon another aspect of seclusion, that, namely, in which it is desirable, not as a therapeutic measure, but as applied to insane criminals, for the protection of the other patients. These criminal inmates are, he says, as a rule, a cunning and dangerous class. Whether their insanity is feigned for the purpose of getting themselves removed to a hospital or not, they do not lose their cunning and dangerous elements of character, and he protests against being obliged to compel the association of other patients with this class, and hopes that this matter will come

before the Legislature in a way to command attention and action.

THERAPEUTIC NOVELTIES.

Our readers must have observed the decided reaction that has been going on during the last ten years from what may be called the dark ages of therapeutics—that period of skepticism, or "therapeutic nihilism," as it has been termed, which succeeded the long and dreary reign of the lancet, the purge, and the sinagogue, in which, having laid aside the commanding air of their predecessors, our craft started at disease in a dazed sort of way, and virtually cried *non possumus* at every turn. This Fabian attitude, it is true, was but the calm that was not to be avoided during the gathering of the forces that were to be led anew to the battle with disease, under the guidance of new leaders. For the time being there was necessarily a standstill that marked the transition from the dominance of tradition to the more enlightened but less assuming sway of observation and induction. The ground had to be cleared of the imposing ruins that had been accumulating for centuries. Reverence for authority having at last come to be recognized as the worm at the heart of medicine, the lesson had to be ground into men's minds that a state of doubting was the only safe starting-point in the quest for a stock of facts on which to found a rational doctrine and practice.

This doubting state of mind was perhaps no more decided in its attitude toward therapeutics than toward pathology, but it was more striking in that aspect, and its longer continuance in that direction was happily regarded as most salutary and most to be maintained. There came a time, however, when observation and experiment would have ended in stagnation, had not some activity arisen in synthetical formulation. Detached data had been lying barren long enough; it was time to "put two and two together." Hence the *renaissance* of medication witnessed during the last few years. Beginning with the topical application of remedies, in which sphere an astonishing range was rapidly disclosed, it soon advanced to systemic drugging. It was straightway ascertained that certain potent drugs could be pushed to more decided action upon the system than had before been thought warrantable; and, on the other hand, it was proved that several agents were capable of acting quite as efficiently in doses that had up to that time been denied any effect whatever, and, of course, without the inconveniences, not to say dangers, that had formerly attended their use.

The next step in the march of therapeutics was the investigation and adoption of many new drugs that proved to be endowed with powers that had never been dreamed of—powers, too, that no agents previously in use possessed. In chloral a true hypnotic was found; in jaborandi we were furnished with a diaphoretic that, so to speak, snapped its fingers at such adjuvant measures as warm drinks and the like; in apomorphine we beheld an emetic that needed not the voluntary swallowing of a bulky dose. New properties were discovered to reside in old drugs, to be sure, and their range of usefulness was surprisingly extended; but it can not be questioned, new is not to

be wondered at, that the fact that unheard-of effects were found to follow the use of substances which before had been either unknown or untried made a profound impression upon the minds of therapists.

The natural result of all this has been to stimulate a search after still other new therapeutic actions, and consequently after novel additions to the *materia medica*. It may well be asked if this rage for novelties is not in danger of being carried too far. It has given rise to a special literature; indeed, there are publications wholly devoted to new remedies, and their pages fairly bristle with an endless array of substances drawn from all three of the great natural kingdoms. We do not deprecate this bare fact, but we do feel called upon to suggest that the ardor of our search in this direction should not be allowed to lead us into giving credence to every apparent instance of a definite therapeutic effect from substances heretofore untried or considered as destitute of any such action. We insist only upon systematic, cool, and deliberate observation, backed up, if need be, by some remnant of the incredulity of a past generation. Certainly, as a matter of practice, it is not wise to be led hastily into novel methods of medication on the strength of the questionable data that largely enter into the constitution of the literature of new remedial agents. So acute a man as the late Dr. Peaslee was in the habit of advising his young friends in the profession to beware of new drugs; and sounder advice, it seems to us, was never given. Most of all should the practitioner avoid the rage for trying new remedies in all conceivable sorts of cases, without any rational guidance, but in a random, and, we must say, perilous way.

THE POLYCLINICS.

It may be said that the promoters of the New York Polyclinic builded better than they knew when they resorted to the word *πολυσ*, instead of *πολυς*, in constructing the title of the institution, for a number of such clinics seem to be springing up among us. Already the Philadelphia Polyclinic and College for Graduates in Medicine has been organized, and its first session, as announced in the advertisement in our last issue, is to open in little more than a fortnight; and we understand that a number of our German *confrères* here in New York are moving in the same direction.

The Philadelphia Polyclinic certainly seems to have been undertaken under most promising auspices, if we may judge from the list of its professors. Dr. Richard J. Levis is to teach operative and clinical surgery, Dr. Thomas G. Morton general and orthopedic surgery, Dr. J. Solis Cohen diseases of the throat and nose, Dr. James C. Wilson diseases of the chest, Dr. John B. Roberts applied anatomy and practical surgery, Dr. Charles H. Burnett diseases of the ear, Dr. Charles K. Mills diseases of the mind and nervous system, Dr. Henry Leffmann "clinical" chemistry and hygiene, Dr. Arthur Van Harlingen diseases of the skin, Dr. Edward L. Duer diseases of women and children, Dr. George C. Harlan diseases of the eye, Dr. J. Henry C. Simes genito-urinary and venereal diseases, and Dr. Frederick P. Henry pathology and microscopy. It will be seen that this is a very

strong array of names, and we doubt not that, under the direction of the gentlemen we have mentioned, the courses of practical instruction given in Philadelphia will be such as to reflect credit upon the profession in that city, and such as to deserve and secure the material success that all who have the improvement of medical education at heart must join in wishing in behalf of those who have engaged in the undertaking.

Concerning the enterprise that our German friends have taken in hand we have less definite information, as no public announcement has yet been made of it, so far as we are aware; but, from what we know of some of the gentlemen who are said to be connected with it, we judge that there is abundant promise in their scheme. The well-known energy of our German physicians and their systematic turn of mind are an earnest that in this matter, as in most others in which they engage, they will prove themselves competent. There is a great number of German practitioners in this city, and elsewhere throughout the country, who deal almost exclusively with their compatriots, and are, therefore, so situated as to be able to follow the teachings of their countrymen to better advantage than those of men talking in a tongue still more or less strange to them, and also to seek naturally for details of practice which, being peculiar to their race, are likely to be more acceptable to their patients than others that, although equally to be commended from an abstract point of view, may not so readily suit the Teutonic mind. In view of all these considerations, it seems to us a foregone conclusion that the German institution for the instruction of graduates will meet with abundant patronage.

Scarcely less than the success of their own school must the extent to which their example is being followed contribute to the gratification of the gentlemen who organized the New York Polyclinic. They may justly feel proud, not only of the creditable career of their own institution, but also of the emulation that they seem to have excited, for it is quite certain that, had their task been performed in a negligent, or perfunctory, or in any way inadequate manner, the word *polyclinic* would have been heard of no more among us. As it is, they will have a constant stimulus to renewed exertion, and we doubt not that they will prove themselves equal to the demand.

FATTY HYPERTROPHIC CIRRHOSIS.

INSTANCES are multiplying in which pathological investigation has outstripped clinical observation, discrediting Velpeau's dictum: "*On ne part pas de l'anatomie pathologique, on y arrive.*" Perhaps the most recent exemplification of this statement is to be found in a peculiar affection of the liver to which M. Sabourin has given the name of fatty hypertrophic cirrhosis (*cirrhose hypertrophique graisseuse*), of which we find an excellent account in an editorial article in a recent number of the "*Progrès médical.*"

It seems that it was M. Cornil whose attention was first drawn to this singular alteration of the liver, and, since that, the affection has been studied by M. Hanot, M. Lancereaux, M. Dupont, M. Rendu, M. Stiépovich, M. Hutinel, M. Sabourin, and M. Merklen. Dupont, working under inspiration from Lancereaux, first threw light on the clinical history of the disease, which he termed acute diffuse interstitial hepatitis. Rendu re-

ported two cases, under the title of subacute alcoholism with accidents resembling those of icterus gravis.

Examined post mortem, the liver is found to be enlarged and of a remarkable cubical shape. It is of a pasty consistence, and shows the yellow color characteristic of fatty degeneration. Glisson's capsule is smooth, although sometimes thickened by perihepatic bands. On cutting into the organ, its texture shows a striking resemblance to that of the subcutaneous panniculus adiposus. As in alcoholic venous cirrhosis, the cirrhotic process begins about the blood-vessels, and invades the biliary ducts only secondarily. The affection of the liver is almost always accompanied by sclerosis of the kidneys, and it is usually found in tuberculous subjects.

As regards symptoms, the disease is commonly latent at first, no decided manifestations being present to point to liver trouble. Months, and perhaps years, are passed with attacks of abdominal pain, a sense of weight in the epigastrium or the hypochondrium, nausea, occasional vomiting, frequent vertigo, sometimes nocturnal delirium or true hallucinations; but finally a hyperæsthesia of the limbs is manifested which continues to the end. The second stage, when a diagnosis becomes practicable, is febrile, with oedema of the limbs or the face, extreme oppression, or profuse sweats. Sometimes a subacute peritonitis suddenly makes its appearance. Sooner or later, with scarcely an exception, there is at least some degree of jaundice, with a tendency to hæmorrhages; but the affection runs a longer course than that of typhoid icterus, with alternating improvement and aggravation. The disease attacks only corpulent persons, and they do not lose their *embonpoint*. Toward the close, signs of pulmonary tuberculosis declare themselves, and the liver is found to be enlarged. This second stage generally lasts four or five weeks, but in some instances there seems to be an interruption of the process, although the symptoms invariably return within a few weeks, and end in death.

Proceedings of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of February 7, 1883.

ARSENICAL PARALYSIS.—Dr. CHARLES K. MILLS read the following paper:

On November 2, 1882, at Norristown, Pennsylvania, occurred a series of cases of arsenical poisoning almost without parallel. The poisoning was brought about chiefly through eating pumpkin-pie, which it was subsequently proved contained a large amount of arsenious acid. The story of the tragedy does not come within my province in the present paper.

On the 24th of December, 1882, I saw one of these cases at Norristown with Dr. E. M. Corson, the physician in attendance. On the 3d of January, 1883, the patient was brought to the Philadelphia Orthopædic Hospital and Infirmary for Nervous Diseases, to be under the care of Dr. S. Weir Mitchell. I am indebted to Dr. Mitchell for great courtesy in affording me the opportunity of thoroughly studying the case at the hospital, and now of presenting it to the college.

Dr. G. B. Massey, Electro-Therapeutist and Assistant Physician to the hospital, carefully studied with me the electrical reactions. The results of our examinations will be given at the proper place. Dr. Browning, resident physician, also rendered assistance in investigating and recording the case.

H. G., aged twenty-four, single, a lawyer, prior to Thursday,

November 2, 1882, was in good health. He was taken sick immediately after rising from the dinner-table, having eaten freely of the pie which was subsequently found to contain the poison. He had an attack of vomiting which lasted a few minutes only. He had several similar spells of vomiting during the afternoon, and from Thursday night until Saturday morning the vomiting was almost continuous. It then began to subside, ceasing entirely Monday afternoon, except that at two o'clock Tuesday morning he vomited a dark grumous mass. Just before vomiting this mass he had a sensation of constriction or contraction in the muscles of the chest and throat, and the facial muscles were much contorted. He was not purged at any time; in fact, his bowels were not opened from Thursday, November 2d, until Wednesday, November 8th. During the whole time that the vomiting persisted he had but little pain, scarcely more than would be accounted for by the retching and vomiting. Prostration was very great from the first. Tuesday night, November 7th, he attempted to get out of bed, but fainted, and remained for some time in a semi-conscious state. About this period he began to have marked fever.

On Wednesday, November 8th, and, therefore, six days after taking the poison, the patient noticed for the first time a sensation of aching and numbness chiefly about the knees. The numbness continued, and, in a few days, extended toward his feet. He still, however, had fair use of his legs, although, of course, they were extremely weak. Three days after the appearance of the numbness in his lower limbs the same sensation began in the fingers of both hands, and soon extended to the wrists, beyond which it never passed.

His brain remained unaffected.

His legs below the knees were now almost completely paralyzed, and there was some loss of power below the elbows.

His face was considerably puffed and swollen.

His general condition and his special symptoms remained as just recorded, without any change worthy of note, until December 1st, four weeks after the ingestion of the arsenic, when he began to suffer great pain. The pains began in the knees, and speedily invaded the legs below the knees and the feet, progressing in the same course as the numbness had previously taken. Aching was always present, but frequently the pains were boring, tearing, or lancinating. They were accompanied by a sensation like that produced by a strong faradic current. Two days after the coming on of the pain in the legs, the fingers and hands also became the seat of aching. In one week the pains began slowly to abate; but throughout December, and, indeed, up to the present time, he has had more or less pain, varying very much in character. By the middle of December, the numbness and aching, which had previously been below the knees, had extended above them a distance of several inches. His lower extremities felt as if incased in a cylinder as high as the limits of the numbness. The symptoms in his upper extremities did not change noticeably. The loss of power in the thighs increased with the spreading upward of the sensory perversion.

I will now give the results of my examinations into the condition of the patient. He was first examined by me December 24, 1882, but the notes here given are from examinations made between January 10 and January 17, 1883, nearly two months and a half after the poisoning.

He presented no brain symptoms, and no disturbances of the special senses of sight, hearing, taste, or smell. He slept fairly well until midnight, and was then usually restless and unable to get into a comfortable position.

He was much emaciated. Wasting of the limbs was extreme. The following measurements were taken:

Circumference of right thigh.....	11 inches.
“ “ left “.....	10 $\frac{3}{4}$ “
“ “ right calf.....	8 $\frac{1}{2}$ “
“ “ left “.....	8 $\frac{1}{2}$ “
“ “ right arm.....	7 “
“ “ left “.....	7 “
“ “ right forearm.....	6 $\frac{1}{2}$ “
“ “ left “.....	6 $\frac{1}{2}$ “

Paralysis below the elbows was marked, but not complete. The extensors and supinators were most decidedly affected. The fingers could only be flexed about one half. Movements of the thumbs and the small movements of the fingers were impaired. The loss of power was slightly greater in the right limb than in the left. The following were the registrations of the dynamometer:

Right hand.....	35
Left “.....	35

At both elbows were marked contractures at about right angles. The angles could be reduced to about 160°, but any attempt to carry the straightening farther caused pain in the flexor tendons.

Both legs were completely paralyzed below the knees. All movements of the toes and feet were abolished absolutely.

The legs in their entirety showed a tendency to rotate outward, the feet, however, assuming the equino-varus position. Contractures were not present at the knees, but at times the limbs would assume a semiflexed position, these acts of flexure being accompanied by cramp pains in the flexor muscles of the thighs. He had these jerkings not infrequently both in the legs and in the arms.

The bowels were very torpid, requiring cathartics. Some dribbling of the urine occurred for a few days in the early part of January, and then passed away. For a few days, also, he had some pain, which he referred to the lower part of the urethra, just as the discharge of urine was completed. At the time of examination, January 17th, the urine was passed slowly, but without pain.

The urine showed an excess of phosphates; but neither albumin nor sugar was present.

Farado-contractility was abolished in all muscles below both knees. Above the knees, the extensor and flexor groups and the sartorius were examined, and the faradaic reaction was found to be greatly diminished, but not wholly absent. The response was better to nerve than to direct muscular applications.

The muscles below the knees would not respond to weak galvanic currents. To currents of medium strength they responded, but not normally.

The reactions were those of degeneration. Anodal closing gave the strongest reaction; cathodal closure came next. Slight contractions followed both anodal and cathodal opening. The contractions were at first sluggish, though vigorous, increasing after a few trials, and then quickly exhausting. The reactions, expressed in the German formula, were:

AnSz; KaSz; AnOz; KaOz.

In both upper extremities farado-contractility was decreased, but not lost; the diminution was much greater below than above the elbows. Below the elbows the faradaic excitability was rapidly exhausted.

To the galvanic current the reactions of degeneration were present, but not so decidedly as in the legs. Anodal closing gave stronger reaction than cathodal. With moderately strong currents, tetany was produced at the anode.

Both patellar reflexes were abolished.

The cremaster-reflex was studied, and presented some inter-

esting points. The retraction of the testicle, known as the cremaster-reflex, which has been thoroughly discussed by Dr. S. Weir Mitchell (“Journal of Nervous and Mental Disease,” October, 1879), can usually be awakened by irritation of a certain definite region of the thigh extending from the groin nearly to the knee. In young lads, as Dr. Mitchell has shown, this reflex is easily caused by touching or pinching the whole thigh, with the exception of a band of skin which nearly always may be represented as forming the postero-lateral third of the circumference of the thigh. Sometimes, however, the cremaster-reflex region is far less, and sometimes far more extensive. It rarely extends below the knees, although, as stated by Dr. Mitchell, it may in the healthy boy include a large part of the calf of the leg. In adults the excitator region is often much restricted, and it may even be absent.

Gentle irritation of the skin of the inner aspect of the right thigh and leg of the patient, as far down as the malleolus, caused very vigorous retraction of the right testicle. Sometimes, but not usually, both testicles were retracted. Similar irritation of the left thigh and leg led to movement of the left testicle, which was marked, but not so vigorous as that exhibited by the right from irritation of the right limb. Now and then, in making this test, the unilateral movement of the left testicle, from irritation of the left thigh and leg, was followed a moment later by an imperfect retraction of the testicle of the opposite side. A similar effect was not produced in any of my examinations by irritation applied to the right limb; neither did excitation of one side cause motion in the other side only.

Dr. Mitchell says: “As a rule, which has infrequent exceptions, irritation of one side produces unilateral movement of the testicle of the same side. There are two forms of violation of this law. In the first, irritation of one thigh causes motion of the testicle of the same side, and also, a moment later, less complete action of the testicle of the opposite side. In the other case, touching or pinching certain parts of the inner and usually of the lower half of the thigh causes reflex cremaster motion on the other side only; while like irritation in other parts higher up gives rise only to unilateral activity on the same side.”

On admission, the surface temperature of each calf was 95° Fahr. He usually complained of his legs feeling to him unduly warm.

Late in November, transverse white bands were observed across the finger-nails, about two lines from their posterior limits. The nails were not furrowed, but simply showed white markings. As the nails have slowly grown, these lines have remained.

The fingers and forearms were hyperæsthetic, but at the same time the patient could not determine with any accuracy as to one or two points, on testing him with the aesthesiometer. A similar condition, but more marked, was present in the feet, legs, and as high as the middle of the thighs. The muscles were very sensitive.

Applications of hot and cold water were discriminated readily.

On admission to the hospital, the following treatment was instituted by Dr. Mitchell: Applications of ice and hot water alternately were made three times daily for ten minutes at a time to his arms and legs from the elbows and knees downward. Surface massage with cocoa-nut oil was used once daily. Ice-bags were applied to the spine for one to two hours twice daily. One grain of the extract of ergot of the new United States Pharmacopœia was given every two hours, and this was rapidly increased until thirty grains daily were administered. After continuing the use of the ergot for a week, the patient's stomach became disordered, and tincture of belladonna, in doses of five drops every three hours, was substituted. Fifteen grains

of chloral were administered occasionally, and sulphate of morphia, at first one twenty-fifth of a grain, and eventually increased to one sixteenth of a grain, was ordered, to relieve pain when necessary.

He was placed on the ordinary full diet of the hospital, with the addition of milk three times daily and beef-tea twice daily.

I will give the record of pulse, respiration, and temperature, for two weeks from January 9th to 23d:

	PULSE.		RESPIRATIONS.		TEMPERATURE.	
	Morn.	Even.	Morn.	Even.	Morn.	Even.
Jan. 9	107	107	24	24	98° F.	99° F.
" 10	134	140	24	24	98° 4	99° 2
" 11	134	132	24	24	98° 6	98° 6
" 12	136	132	24	24	98° 8	99° 1
" 13	140	128	28	24	98° 6	98° 8
" 14	140	138	24	28	99° 8	98° 8
" 15	140	140	24	24	99° 4	98° 4
" 16	136	128	24	24	99°	98° 8
" 17	148	128	24	28	98° 8	99° 6
" 18	136	124	24	24	99°	99° 8
" 19	132	116	24	20	98° 4	98° 6
" 20	124	116	24	24	98° 6	98° 6
" 21	130	116	24	24	97° 8	98° 6
" 22	128	120	24	24	98°	98° 8
" 23	124	136	24	25	99°	99° 4

The pulse, therefore, during the time of these observations ranged between 107 and 148, and was nearly always more rapid in the morning than in the evening.

The respirations ranged between 20 and 24, standing usually at about 24.

The temperature ranged between 97° 8' and 99° 8' Fabr., but commonly was not much either way from the normal.

I made an examination of the patient to note the effects of treatment to-day (February 7th). He has improved steadily day by day. His general strength has increased. He has regained almost entirely the use of the muscles above the knees. He has also much better use of his forearms and hands, particularly the latter, being now able to pick up small objects. The "wrist-drop" has improved greatly. He has much less pain, aching, and numbness below the knees; the legs below the knees, however, still remain paralyzed, but are not so completely helpless. He has every appearance of progressing steadily to recovery.

Having presented this case as fully as possible, I will give in a few words all the information I have been able to obtain as to paralysis and other nervous symptoms shown by the other victims of the poisoning:

Six others altogether, besides our patient, were poisoned. One of these was a little boy, four years old, I. S., to whom a piece of the fatal pie was given, as a reward for going on an errand. He died within ten hours, and I have no knowledge of observations as to paralysis or other manifestations of involvement of the nervous system. Probably his death occurred too soon to allow any such observation to be made.

M. S., a sister of the little boy, ate a very little of the pie, and suffered to some extent, but not seriously.

C. H. G., the father of the patient, died November 8th, six days after the ingestion of the arsenic. Besides severe gastro-intestinal symptoms, he suffered with pain in his head, back, and limbs, was delicious for some hours, and was almost completely paralyzed.

Mrs. G., mother of the patient, ate a little of the pie, November 2d, and had an attack of vomiting. On the 4th she ate a piece of custard, which was also found to contain arsenic, and was attacked with vomiting. A few days later, weakness of the legs, with aching and numbness, came on, and the right foot

and leg became swollen and inflamed. She gradually recovered.

Mrs. V. ate a mouthful or two of the pie and custard containing the arsenic, and suffered with vomiting, etc., for three days. She has since had paresis and paræsthesia of the legs.

Mrs. F., who ate freely of the poisoned food, suffered severely from gastro-intestinal symptoms. She is now under the professional care of Dr. H. N. Umstead, of Yerkess P. O., Montgomery County, Pa., who has courteously written to me about her condition, and the substance of whose communication I will give. Dr. Umstead states that Mrs. F. has been paralyzed from the elbows to the ends of her fingers, and from the knees to the toes. She complained of numbness and coldness in the limbs, and a feeling as if a cord was tied tightly around the waist. She had extreme pain in the paralyzed extremities. She has greatly improved, is riding out daily, can stand without aid, and can even walk a little with assistance. She still has some pain in the hands and in the soles of the feet, but they are not tender to the touch. She has some anæsthesia of the hands and feet, especially of the latter. She begins to enjoy her food, for which at first she had great loathing. Her bowels are moved once, and she urinates twice daily, but has not quite the natural sensation when the bowel or bladder is evacuated. Dr. Umstead states that Mrs. F. and Mrs. V., whom he also treated, make five cases of arsenical paralysis which have fallen under his care during his professional career.

A careful analysis of the history and symptomatology of the case detailed must compel me to conclude that in well-marked arsenical paralysis we have to deal with a diffused myelitis, decided motor, trophic and sensory bilateral phenomena being present.

With the assistance of Dr. J. H. Lloyd, one of the staff of the nervous dispensary of the University Hospital, I began the preparation of a *résumé* of the literature of arsenical paralysis, when the "Journal of Nervous and Mental Disease" for October, 1882 (edited by William J. Morton, M. D., of New York), containing an admirable article on the subject by Professor E. C. Seguin, came to hand. In this paper the literature of the subject is given with considerable fullness, and to it I would refer those interested.

Beginning with Abano, who flourished as early as the thirteenth century, the authorities quoted or referred to by Professor Seguin are Forestus, Zacchias, Hahnemann, Thilenius, Brodie, Orfila, Christison, Graves, Fluss, Leroy d'Étiolles, Imbert-Gourbeyre, Smoler, Jaccoud, Seeligmüller, Popow, Rosenthal, Romberg, Erb, Hammond, and Da Costa.

I will refer here only to the observations of Christison and Popow. Christison describes two classes of cases of arsenical poisoning in which the victims die early without paralysis, and a third class of what he terms subacute cases, with moderate gastro-intestinal inflammation. "In the latter stage these cases are apt to show marked nervous symptoms: coma, epileptoid attacks, mania, tetanus, hysterical seizures, partial paralysis, resembling lead paralysis in affecting the extremities; contractures may exist."

In 1881, Popow, of St. Petersburg, published an essay upon the pathological anatomy of arsenical paralysis, as produced artificially in animals. The work of Popow was carried on under the guidance of the distinguished neurologist and microscopist, Professor Mierzejewski, and Seguin considers his essay as in many respects the most important contribution yet made to the subject. Popow concludes that arsenic, even in a few hours after its ingestion, may cause acute central myelitis or acute poliomyelitis; that in chronic cases pathological changes are found in the white as well as in the gray substance, constituting a diffused myelitis, and that the peripheral nerves remain

normal, even three months after intoxication. Seguin gives condensed accounts of a few of the cases reported in the literature of the subject, and also reports three cases of his own—all would-be suicides with Paris green. His conclusions are practically the same as those of Popow. According to Seguin, whether the myelitis is strictly arsenical—i. e., caused by the direct effect of the arsenic on the tissue of the spinal cord—or whether it is produced (as are many forms of myelitis) by the irritation of the peripheral nerves (cutaneous, intestinal, and gastric nerve-endings), is a question which can not at present be definitely solved, but which presents an interesting field for future research and speculation.

Dr. Lloyd has collected the following references to authorities and cases in addition to those cited by Seguin:

Beck ("Elements of Medical Jurisprudence," sixth edition, vol. ii, 1838) gives three classes or varieties of arsenical poisoning. In the third variety there is, first, the inflammatory action; then, when this recedes, comes the second stage, that of nervous involvement. The nervous symptoms vary "from coma to an imperfect palsy of the arms and legs, and between these extremes are observed epileptic fits or tetanus."

Taylor ("On Poisons, etc.," 1848) gives several cases where the symptoms of *narcotism* (or general paralysis of the nervous system) were marked.

A man swallowed, by accident, some arsenic early in the morning. He went to work for several hours afterward, and was then gradually observed to sink into a drowsy state, and died that night with no complaint of pain.

A child, aged two and a half years, died *narcotized* two hours after taking the poison.

Wharton and Stillé ("A Treatise on Medical Jurisprudence," second and revised edition, 1860) make mere mention of palsy as a symptom which is apt to occur late in the case.

Taylor ("A Manual of Medical Jurisprudence," seventh American edition, 1873) speaks of local paralyses, preceded by numbness or tingling in the fingers and toes, as common consequences of chronic arsenical poisoning.

According to Stillé ("Therapeutics and Materia Medica," fourth edition, vol. ii, 1874, p. 816), arsenical paralysis most frequently affects the lower limbs first, extending gradually to the arms; but it is more permanent in the legs, continuing for months or even years. It is accompanied with cramps, spasmodic movements, numbness, and formication. The cutaneous sensibility is impaired, and the patient generally complains of coldness in the parts affected.

H. C. Wood ("A Treatise on Therapeutics, etc.," second edition, 1876) speaks of paralysis which follows non-fatal cases, and affects preferably the lower extremities, commencing and remaining longest in them; does not select the exterior muscles, and is almost always accompanied by anesthesia, or at least by numbness and formication, and by coldness of the extremities. He quotes experiments on frogs, mostly from Sklarek.

Ringer ("Hand-Book of Therapeutics," ninth edition, 1883) refers to his experiments on frogs. He found paralysis of sensation, reflex action, and voluntary motion. He believes that the paralyzing action is exerted on the cord first, then on the nerves, and last on the muscles. The difference may be noted between Ringer and Seguin, that Ringer does not refer all pathological changes to the cord. He regards the arsenic as a "protoplasmic poison," affecting all tissues. He says that frogs are sometimes only apparently paralyzed, i. e., sensation is lost, and hence there is no response to external irritants, but, if laid on their backs, they turn themselves over.

"The Index-Catalogue of the Surgeon-General's Office" gives the titles of forty-three books on the physiological and

therapeutic effects of arsenic, but nothing special on its paralyzing effects.

Gibb ("Neuralgia and Paraplegia, supposed to be due to long-continued use of arsenic, etc.," "Trans. Path. Soc. Lond.," ix, p. 442) records the case of a lady who had taken arsenic, mostly Fowler's solution, for many years for a skin affection. She had attacks of acute neuralgia in groins, shoulders, and sides. These pains were considered due to arsenic by Sir James Clark, Dr. Robert Lee, and Dr. Copland, who all saw the case. Afterward she lost all power over her lower limbs, which felt numb, although sensibility remained perfect. This retention of sensibility is at variance with other observers and experimenters. After death the abdominal and thoracic glands were found enlarged, and traces of arsenic were found in the liver and in the lumbar vertebrae, although the drug had not been taken for more than seven months before death.

Colton ("Arsenical Paralysis," "N. Y. Journ. of Med.," Sept., 1850, pp. 177, 178) mentions the case of a patient who accidentally swallowed some arsenic, and was admitted to the hospital under Dr. Colton's care. The primary effects of the poison had been successfully combated with proper remedies. Seven days afterward, when feeling quite well, he was attacked with violent cramps in the index finger of the right hand, spreading to other fingers, then to the other hand, and finally to the feet. The pain in the hands subsided as the feet became affected. The cramps lasted thirty minutes. He then fell into a sound sleep, it being night, but in the morning he found, to his surprise, that he had lost the use of the affected parts. This paralysis had continued unchanged for five months. There was also a feeling of heat and numbness in the arms from the fingers to a little below the elbows, and in the legs from the toes to a little below the knees. Lancinating pains also occurred in those parts daily from 5 p. m. to midnight. He improved slowly under the use of quinine, strychnine, and electricity.

McCready ("Death from External Application of Arsenic," "Am. Jour. Med. Sci.," July, 1851, p. 259) relates that a woman rubbed white arsenic mixed with gin on the head of her child suffering with favus. The child died in less than forty-eight hours, with its legs completely paralyzed.

MacLagan ("On the Arsenic-Eaters of Styria," "Edinb. Med. Jour.," 1864, p. 200) visited Styria in the year 1864, and had personal interviews with two "arsenikophagites," one of whom ate in his presence nearly five grains of arsenious acid, and the other nearly six grains. The urine of both of these men was carefully bottled and taken back to Great Britain, where a chemical examination revealed arsenic. The physiological effects on these toxicophagi are described as being only tonic and stimulant, especially improving the wind and increasing sexual desire. MacLagan's evidence is strong, yet perhaps not such as would be received in a court of justice, as the men were not kept continuously under observation. The point of chief interest is that he says nothing about paraplegia or any acute or chronic poisoning symptoms among these arsenic-eaters.

Dr. Lloyd has called my attention to a case, not before reported, of suicide with arsenic, which happened some years ago in Bucks County, and was under the care of the late Dr. Hendrie. Anesthesia and paralysis were so marked that the man declared that his legs were cut off, and died in that belief.

Dr. S. WEIR MITCHELL asked if the urine had been examined with care in the early stages of the case. Of late there had been no evidence of trouble, and, if at a former period there was albumin, it was no longer present. Perhaps it was not known to all the Fellows that arsenic, in medicinal doses, was in rare cases, as Dr. Mitchell pointed out many years ago, the

cause of more or less albuminuria. As concerned diagnosis, Dr. Mitchell had always looked on these grave forms of paralysis from arsenic as due to myelitis, and saw much in this case to support and nothing to oppose this opinion. Among the symptoms on which the author of the paper had dwelt least were the frequent twitches of the limbs, especially in sleep, and the intense general tenderness of the muscles, which disappeared readily under the use of massage. The pearly tinted band on the nails, about one line wide, had not the slightest indentation, and was unlike anything in the way of an indication of arrest of nail growth which has ever come to Dr. Mitchell's attention.

Dr. ROBERTS BARTHOLOW said that these forms of arsenical poisoning, affecting the nervous system, as described in the very interesting paper by Dr. Mills, presented many remarkable features. It had long been known that there were cases in which profound depression of the nervous centers, coma, and insensibility had been caused by large doses of arsenic, without any local irritation—without gastro-intestinal inflammation. On the other hand, Virchow informed us that there were cases of acute arsenical poisoning which could not be differentiated, either in respect to the symptoms observed during life or in the morbid anatomy, from the algid stage of cholera. The author of the paper had not referred to the fatty degeneration of the intima of the vessels, or to the same change occurring in the epithelial structures of various organs, but he had given an account of the other changes, all of which showed the profound alterations to which the tissues of the body in general were subjected, and which tended to prove the correctness of Ringer's view—that arsenic was a protoplasmic poison, and as such left no part of the organism untouched. There was doubtless a community of actions among the poisonous metals, and all affected the system to a less or greater extent in the same way. The metals were so largely employed in trades and in domestic life in our day that many cases of obscure nervous diseases might have their origin in this way. In respect to the treatment pursued, he would have directed more attention to securing elimination of the poison. However, on this point it must be admitted that the time during which elimination could be effected was rather short. The chemists told us that if, in a fatal case of arsenical poisoning, the patient lived a week after the poison had been swallowed, its detection might be impossible, so rapidly was it eliminated.

In reply to Dr. Bartholow, Dr. MITCHELL said the time for attempts at elimination had passed, as two months had elapsed between the poisoning and the patient's admission to the hospital.

Dr. S. W. GROSS asked whether any observations had been made with regard to the genital functions in the case reported.

Dr. J. T. ESKRIDGE said that the lecturer had not referred to changes in the blood in acute arsenical poisoning. Brodie, quoted in Stillé's work on "Materia Medica and Therapeutics," observed a fluid condition of the blood in animals poisoned by arsenic. He called attention to the fact, because it was another proof of the profound devitalizing influences of the drug when taken in toxic doses.

Dr. MILLS, in reply to the questions which had been asked, stated that there was impairment of the genital functions, but that sexual desire and evidences of sexual power were present. So far as he knew, the urine had not been examined in the early stages of the case. Efforts were made by Dr. Corson, under whose care the patient came, to eliminate the poison by cathartics. When he saw the patient first, the time had passed to derive much benefit from this plan of treatment. Iodide of potassium was administered.

Reports on the Progress of Medicine.

QUARTERLY REPORT ON OPHTHALMOLOGY AND OTOTOLOGY.

No. XIII.

By CHARLES STEEDMAN BULL, M.D.

LECTURER ON OPHTHALMOLOGY AND OTOTOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO THE MARINE HOSPITAL FOR CHILDREN, AND TO THE SURGEY AND CHILD'S HOSPITAL.

OPHTHALMOLOGY.

THE BLOOD CIRCULATION IN THE REGION OF THE YELLOW SPOT.—Ayres ("Arch. of Ophth.," xi, 4), in the course of numerous experiments for determining the exact anatomy of the distribution of the blood-vessels around the macula lutea and fovea centralis, has hit upon the following beautiful and easy way: He puts homatropia in the eye, and then stands with his back to a common gas flame, and so adjusts a plain gold ring close to the cornea that its convex surface will throw a blurred image of the light into the eye. The slightest movement of the ring will cause every capillary around the macula lutea to be seen with the greatest distinctness. An ordinary teaspoon, placed in the same way, will give a larger area. It makes no difference in this experiment whether the spoon or the head be moved, since in either case the shadows will fall on the retina in places where they are not accustomed to fall. Either the spoon or ring, or the head, must remain stationary while the other is moved. If we open the other eye and look toward a piece of paper, the vessels will be seen as if projected on the paper.

THE INFLUENCE OF RIGHT OBLIQUE WRITING UPON THE EYE AND THE POSITION OF THE CHILDE. BORN (Ber. d. oph. Ges.: Beilageheft d. "Kl. Mon. f. Aug.," 1882) states that in right oblique handwriting there exists a constant relation (proportion) in the direction of the line of union of the centers of rotation of the two eyes in such a manner that the base line projected to the point of the pen cuts the line running from upward and to the left downward and to the right at a considerable angle. He then proposes to himself to find out what is the law which forces the writer with irresistible power to adopt this definite direction of the base line, and, consequently, to assume the before-mentioned position of the body. By standing behind a child while writing, he has noticed that the down strokes were always made approximately perpendicular to the base line projected to the point of the pen. He found that the angle, under which the base line projected to the point of the pen cuts the line, is equal to the angle which the perpendicular erected upon this line makes with the down stroke. The result of his measurements led Berlin to the conclusion that it is not the oblique handwriting in itself which is injurious, but only its connection or union with the straight position of the copy-book.

EYE DISEASES FROM MASTURBATION.—Ayres ("Arch. of Ophth.," xi, 4) considers that onanism, when practiced excessively, can produce persistent photopsia, conjunctival inflammation, blepharospasm, paresis of accommodation, insanity, hypochondria, writer's cramp, and tabes. In a certain number of cases he has found photopsia or subjective perceptions of light in young persons whose eyes showed a normal condition of the pupil, acuteness of sight, tension, sense of space, light and color, refractive media, optic nerve and retina. In all the cases both eyes were affected. The dazzling was only once accompanied by a feeling of pressure in the eyeballs, but the photopsic manifestations led several times to real photophobia, and were in many cases so troublesome that reading had to be interrupted after a shorter or longer period.

THE MATURITY OF CATARACT; ARTIFICIAL RIPENING, CORRECTION, AND EXTRACTION OF THE ANTERIOR CAPSULE.—Förster ("Arch. f. Augenheilk.," xii, 1) begins his article with the generally accepted statement that there are many cases of cataract that have been ripe for years in which the iris, nevertheless, casts a shadow upon the lens, and in which the pupil may still be more or less illuminable; while, on the other hand, there are immature cataracts in which the iris casts no shadow on the lens, and in which no illumination in the slightest degree of the pupil can be produced. He divides ripe cataracts into three classes: 1. Those in which there is no doubt of maturity, and in which the mother-of-pearl glistening, sector-like figure is absent from its surface. These cataracts are white, yellowish, or yellowish-gray. 2. Those cataracts which have a large brownish-yellow nucleus, which nearly fills the entire capsule. The pupil is often more or less illuminable, and the iris often casts a distinct shadow. 3. Certain very slowly growing cataracts, with small, bright yellow or white nucleus and half-transparent cortex. Those cataracts in which the opaque cortex shows a distinct sector-like marking, with a glistening mother-of-pearl or tendinous appearance, are to be regarded as immature, in spite of there being no shadow cast by the iris, and no possibility of illuminating the pupil. Förster has seen in some cases the ripening of an immature cataract hastened by an iridectomy. Another means to the same end which he has employed is a light rubbing or stroking pressure made upon the cornea with the knee of a strabismus hook or a pair of closed iridectomy forceps; and he has himself seen a marked change in the sector-like figures produced by this manipulation. Care should, of course, be taken not to make this pressure too hard. Where an iridectomy is to be done to break up posterior synechia, he advises this manipulation to be done before the operation. The energetic use of atropine is also necessary, both before and after the operation. He has never seen any injurious effects produced upon either iris or lens by this manoeuvre. He recommends it, also, to prevent prolapse of the edges of the cut iris in the angles of the wound after iridectomy. He deems the removal of the anterior capsule with the cataract very necessary, as tabs of this torn capsule are so often the cause of serious trouble after operation, by healing in the wound. By removing the anterior capsule, we likewise prevent any considerable amount of cortical substance remaining behind in the capsule. Its removal is best secured by introducing a pair of fine, straight toothed-forceps into the wound and seizing the capsule, in whole or in part, after the extrusion of the lens.

LYMPHADENITIS CONJUNCTIVÆ.—Goldzieher ("Centralbl. f. prakt. Augenheilk.," Nov., 1882) describes a very interesting case of lymphadenitis of the conjunctiva in a boy fourteen years of age. The disease had existed for ten days, and showed a lymphatic gland, as large as a pigeon's egg, near the right ear, a mass of enlarged glands beneath the angle of the lower jaw, and another in the neck. The lower lid of the right eye was slightly swollen, and projected away from the eyeball; the ocular conjunctiva was oedematous and slightly injected. On evertng the lower lid, there was seen in the outer half of the fornix a small tumor, as large as a hazel-nut, situated in the conjunctival tissue, but not adherent to the sclera. The surface of the tumor was uneven and yellowish, as dense and hard as a chance of the conjunctiva. There was no ulceration, nor any trace of trachomatous infiltration or papillary proliferation. The case was, therefore, a circumscribed tumor-like lesion of the conjunctival fornix, tending to caseous infiltration, which doubtless appeared in connection with marked infiltration of the lymphatic glands connected anatomically with the diseased region, and occurring in a person of scrofulous constitution. Goldzieher was at first inclined to regard the case as one of

primary tubercular nodular deposit in the conjunctiva, though differing decidedly from the cases of conjunctival tuberculosis hitherto described. He removed the tumor with the scissors without any difficulty, and the wound readily healed. A microscopic examination, however, caused him to change his opinion as to the nature of the disease, and he declares it to be a case of acute lymphadenitis of the conjunctiva, a real inflammatory hyperplasia of glandular tissue.

REMARKS ON 177 OPERATIONS FOR ENTROPION AND TRICHIASIS.—Hotz ("Arch. of Ophth.," xi, 4) in this paper again advocates the advantages of the operation devised by himself and previously described. The essential features of the operation are as follows: The skin of the eyelid is incised transversely in the line of the upper border of the tarsus of the upper lid (or along the lower border of the tarsus of the lower lid); the muscular layer covering that border of the tarsus is excised (about 3 to 4 mm. in width); and the cutaneous edges of the incision are brought in close adaptation with the tarsus by sutures which are passed directly through the border of the tarsus and the tarso-orbital fascia. The incision should follow as closely as possible that furrow which is the border-line between the skin of the eyelid and the supra-tarsal integument. In the upper lid this furrow describes a curve beginning two millimetres above the inner canthus, and ending two millimetres above the outer canthus, but its center is from six to eight millimetres removed from the cilia. Only when the tarsal skin becomes firmly united with the border of the tarsus is the permanent success of the operation insured. Hotz claims for the operation the following advantages: 1. It accomplishes its purpose without the slightest destruction of skin. 2. For this reason it can be employed in cases where other methods are impracticable on account of excessive shortness of the skin of the lid. 3. It does not mutilate the lid nor in any way interfere with its movements. 4. In a case of relapse it can be repeated without in the least disturbing the natural appearance of the lid. 5. The tension by which the inverted lashes are turned back to their normal position is rendered independent of the movements of the lid, because the distance between the two points, upon which the tension is to exert its influence, remains the same whether the lid is raised or dropped.

THE ORIGIN OF DETACHMENT OF THE RETINA.—Leber (Ber. d. ophth. Ges.; Beilageheft. d. "Kl. Mon. f. Aug.," 1882) considers that the spontaneous perforations in detachment of the retina in man, which are sometimes observed, are necessarily and closely connected with the mechanism of origin of the detachment. This might be regarded as a settled fact if it could be proved that in all cases of sudden detachment a perforation of the retina exists from the beginning, immediately after the occurrence of the detachment. During the last two years he has carefully searched for the presence of such a retinal perforation in every case of detachment which came under his observation; and he has found it so frequently in all cases, recent and old, that he is inclined to regard it as constant. He has found this perforation constantly in that portion of the retina where the detachment began. He has found that the sudden occurrence of the detachment without change in the intraocular tension is explained by the appearance of a perforation, which facilitates transudation into the vitreous chamber beneath the retina. For the maintenance of the view that the detachment and perforation as a rule result from a sudden pull or tension from within, there is still wanting an important factor, namely: the proof of a process which might exert a strain upon the inner surface of the retina, which can only be furnished by an anatomical examination. This proof he thinks he can furnish. It is well known that in old cases of detachment marked chronic inflammatory changes are found in the retina, which have hith-

erto always been regarded as secondary changes resulting from the detachment. Leber thinks it is much more likely that this process lies at the root of the matter, and only gradually advances to complete atrophic degeneration.

THE ASSOCIATION OF SOUNDS, ESPECIALLY OF WORDS, WITH COLORS.—Mayerhausen ("Kl. Mon. f. Augenheilk.," Nov., 1882) reports a sixth case of this very rare condition, occurring in an educated lady, aged twenty-five, the wife of a physician. In early childhood she connected the sounds of words with certain colors, and thus judged of the beauty of names. Words of one syllable were always perceived of a single color. If words of several syllables were rapidly spoken, they appeared of the color of the most accented syllable; but, if slowly spoken, each syllable had its own color. She convinced herself that the color depended solely on the sound of the words by the fact that in words of a foreign language the color depended upon their pronunciation, and not upon the way that they were written. It is not the person or the thing represented by the word which appeared colored, but only the *spoken* or *heard* word. She has always perceived the same color with the same word-sound; and this sensation is unavoidable; it can not be any other color than the one at first and always perceived. It is especially the sound of vowels which calls forth the sensation of color. Pronounced green she has never perceived; the word "green" sounds milky-white to her; and, although sky-blue is her favorite color, she never perceives it from the sound of any word. Mayerhausen tested her with a series of more than two hundred words from various languages, and the colors corresponding to the various sounds were given by her on the spot and without change or misplacement. The patient possessed an extremely finely developed color-sense. In this case it was firmly established that the colored sensation for vowels and their union with consonants was the primary sensation, and the transfer or assignment to actual words with meaning in the analogy of sound was secondary.

TREATMENT OF GRANULAR CONJUNCTIVITIS WITH ABRES PRECATORIUS (Jequirity).—Moura Brazil ("Ann. d'Oc.," Nov.-Dec., 1882) gives an account of the new remedy, jequirity, in the treatment of acute and chronic granular conjunctivitis, and the method of preparing it for use. The seeds of the plant are boiled in water for several hours, or are left to soak in cold water for several days. When they are softened, the spermo-derma is removed, and the seeds are then reduced to a fine powder, which is left to macerate for twenty-four hours in the night-dew. Then it is filtered. With this decoction the patient is to bathe his eyes three times a day. When the liquid is more concentrated it is dropped into the eye for three days in succession, and then stopped for a period. Immediately after the first application the patient begins to perceive a burning, lachrymation, heat and weight in the eyelids, and the next day the inflammation is so intense that the patient can not open his eyes. The skin of the lids becomes shining, of a violet color, the conjunctival ecchymosis is marked, there is a more or less abundant muco-purulent secretion, and intense pain. By reducing the number of seeds in the decoction, the reporter was enabled to produce a moderate inflammation, which sufficed to cure the granulations in a few days. He has also employed the greenish extractive principle of the plant in the form of an infusion of twenty centigrammes to ten grammes of distilled water, and with most excellent results. Cases of granulations, which had lasted for years, and which had resisted all known methods of treatment, have been cured by jequirity in from twenty to thirty days.

INJURIES OF THE BRAIN AND SPINAL CORD WITH CONSEQUENT OCULAR LESIONS.—Nieden ("Arch. f. Augenheilk.," xii, 1) reports a number of interesting cases of this nature in detail.

The first two cases were miners with a fracture at the base of the brain, amaurosis of the left eye, temporal hemianopsia, paralysis of the right external rectus, and diabetes insipidus. The third was also in a miner, with a perforating wound of the left temporal bone from a knife-stab, right hemiplegia without hemianesthesia, paralysis of the left abducens and sensorial aphasia. The fourth case was also in a miner, with concussion of the spinal cord and brain. At first the symptoms were slight, but, later, progressive ataxy appeared, with exophthalmus of both eyes, atrophy of the optic nerves, and slow improvement in the general health.

TREATMENT OF GLAUCOMA.—Pflüger (Ber. d. oph. Ges.: Beilageheft d. "Kl. Mon. f. Aug.," 1882) contributes an interesting article upon the treatment of the various stages and forms of glaucoma. He takes up the old subject of the supposed effect of atropine in diminishing the intraocular tension, in order to counteract the widely extended disbelief in this theory. In all his own experiments he has found that atropine always diminishes this tension and never increases it. In experimenting, again, with eserine, he finds, as he had done before, that, in from ten to twenty minutes after instillation of the drug, the tension gradually increases as well for the whole eye as for the vitreous chamber alone. This, of course, in the healthy eye. The duration of this increase of tension is for a number of hours. He believes that atropine and pilocarpine under physiological conditions diminish the intraocular tension, while eserine primarily increases it. Atropine acts as a specific poison upon the smooth muscular fibers or their nerve-terminations—that is, upon the muscular tissue of the iris, ciliary body, and vessels. Pilocarpine acts upon the glaucomatous eye, not only by its primary action in diminishing the tension, but also by the myosis which it produces, which, however, is much weaker than that produced by eserine. It is indicated in all cases in which the primary effect of eserine is to be feared; but, on the other hand, its use is to be helped by an occasional instillation of eserine in those cases where it can not of itself bring about myosis. Pflüger then formulates his therapeutical indications in glaucoma as follows: 1. Every simple glaucoma should first be treated carefully with myotics. 2. In those cases with normal pupil and anterior chamber, without increase of the intraocular tension, in which, besides the functional disturbance, there exist only the pseudo-excitation and the atrophy of the optic nerve, as well as in the rare cases of subnormal tension, he recommends small doses of eserine (one-fourth-per-cent. sol.) morning and evening for months, and even years. 3. In glaucoma simplex with increased tension, the myotic action of eserine and pilocarpine is all-important, unless the increase of tension is very marked. 4. If myotics fail to reduce the tension in simple glaucoma, he recommends iridectomy in preference to sclerotomy, as more lasting in its effects upon the tension. 5. Certain rare forms of acute glaucoma simplex should be treated with often-repeated instillations of a two-per-cent. solution of pilocarpine; as also that very rare form of glaucoma simplex with abnormally deep anterior chamber and increase of tension. 6. Traumatic glaucoma is best treated with eserine, and if this fails, then by iridectomy. 7. Acute and chronic inflammatory glaucoma is at first best treated with eserine, as preparatory to iridectomy. 8. Eserine is also to be recommended in absolute, or almost absolute, glaucoma with movable iris. In absolute glaucoma with wide, immovable pupil, and a narrow, atrophic edge of iris, adherent to the cornea, eserine may occasionally do good, but sometimes does positive harm. In the latter class of cases sclerotomy is to be preferred to iridectomy. 9. In congenital hydrophthalmus, congenital glaucoma, and glaucoma with aphakia and iridewidening, sclerotomy is to be preferred to iridectomy, preceded and followed by the use of eserine. 10. Secondary

glaucoma demands, in the majority of cases, operative treatment, and here a broad iridectomy is the only sure means of relief.

AMYLOID DEGENERATION OF THE EYELIDS.—Rählmann ("Arch. of Ophth.," xi, 4) is of the opinion that the first appearance of the amyloid degeneration must generally be placed in the deeper strata of the conjunctiva. From there the degeneration seems to advance on the one hand toward the epithelium, and on the other toward the tarsus. New investigations have convinced him that all the layers of the lid, not excluding the epithelium, muscles, and glands, may be involved. The lymphoid cells play a prominent part in the true degeneration. While in most of the cases examined the epithelium was intact, in several there was noticed a hyaline, lustrous condition of isolated groups of epithelial cells. The smaller as well as the larger blood-vessels are frequently found intact. While the walls of the blood-vessels are frequently found diseased, they show fewer changes than the other tissues. While the capillaries and smaller vessels show no peculiar stratification in the products of degeneration, transverse sections of the larger arteries exhibit all the stages of degeneration. The adventitia is usually less advanced, in the process of degeneration than the media. Here the degeneration leads to the inference that the smooth muscular fibers early undergo degeneration. The fibers of the orbicular muscle are usually affected before the tough connective-tissue fibers of the tarsus. The primary stage of the hyaline as well as of the amyloid degeneration is frequently limited to circumscribed places in the continuity of the muscular fiber. The fiber at these points shows distinct nodular swellings, appears varicose, and loses the appearance of striation. The nodules at first look glassy; later they show the amyloid reaction. The subconjunctival tissue is frequently the principal seat of the whole affection. In such instances, sclerosis of the connective-tissue fiber bundles plays a great part. In one class of cases the swelling of the lid is comparatively insignificant, but the degeneration is unusually pronounced. The moderately swollen tissue is hard and fragile. The fracture-surface is uneven, and the prominent granules upon it appear like fish-spawn or boiled sago. In a second class of cases the swelling of the tissues is much more extensive. The intumescences have the appearance of lymphoid tumors. The swelling of the parts chiefly results from a proliferation of the conjunctival adenoid tissue. Besides these changes, the deep, and even the tarsal, connective tissue is markedly sclerosed. The nuclei of the hypertrophied connective tissue show similar changes. The granulated appearance on slightly magnified specimens, resulting from lymphoid cells scattered through the stroma of the conjunctiva, is lost; the cells coalesce; the tissue assumes stiff forms, as if impregnated with hardened wax. In advanced cases, as long as the tissue is not decayed, the stroma is frequently free from the degeneration.

TUBERCULOSIS OF THE IRIS.—Küter (*ibid.*) reports a case of this rare disease in a male child two years of age. The lateral half of the anterior chamber was filled with a cheesy mass, which was in contact with the posterior surface of the cornea. The cornea was transparent, but showed a newly developed blood-vessel. In the medial half of the iris gray miliary nodules were here and there visible to the naked eye. The pupil was closed by a thin exudation. Above, in the sclera, near the corneal margin, was a prominent yellowish-white nodule. An attempt was first made to evacuate the cheesy mass. A long lance-cut was made in the corneal margin, and a piece of the iris was drawn out and excised. It was found impossible to evacuate the cheesy mass, because it was attached to the scleral nodule. A mass of granulating tissue soon grew out of the wound, and one month later the eye was enucleated. A careful microscopic examination of the parts showed the case to be one of

tuberculosis of the iris, which, beginning in the miliary form, gradually developed into a tubercular infiltration of the whole iris, and also involved the corneal wound. Subsequently, cyclitis occurred with anterior and posterior adhesions to the iris, and partial clouding of the lens.

THE PHYSIOLOGY OF THE MOVEMENTS OF THE IRIS.—Schadow's article ("Arch. f. Ophth.," xxviii, 3) will, perhaps, admit of some adverse criticism. He formulates his conclusions as follows: The refraction of an eye can not be regarded as preserving for the diameter of the pupil. In youth, the pupil is wider than in old age, its maximum being from 2 to 3 times, its minimum from 1 to 1.5 times wider. The middle period of life shows the greatest individual differences. Sensory and psychical impressions may be offered as explanatory of this condition of affairs. The constant irregular variations in the size of the pupil must be referred to the change of sensory and psychic irritations. The pupil becomes gradually wider under the lasting effect of the same illumination. This increase, as well as the so-called light-reaction, which consists in rapid contraction with subsequent slow and moderate dilatation, is probably intimately connected with the intensity of perception of the fovea centralis.

THE OPTICAL CONDITIONS OF DOUBLE PUPILS; A DEFENSE OF THE OPERATION FOR ARTIFICIAL PUPIL WITH INTACT SPHINCTER.—Schulek (*ibid.*) has a very long and exhaustive article upon this subject. He begins the discussion as follows: 1. The two light-points of an object visible in Scheiner's experiment and through a double pupil are not two points, but a circle of dispersion. 2. There is no essential connection between the shape of the circle of dispersion and the collective shape of the retinal image. 3. In double pupils, the sensory impression corresponding to the individual circles of dispersion differs from that of coalescing pupils only in being wanting in the blind spots. The confusion in projection is limited to the group of visual elements embraced by the individual circles of dispersion. Whatever lies outside of their range is perceived undistorted in the usual manner. No defect can exist in the projection if the outermost circles of dispersion lie at least so far from each other that their blind spots do not overlap. If, on the contrary, the blind spots of the limiting circles of dispersion overlap, then all light-irritation is wanting in the region of this overlapping, and there is an empty spot in the retinal image as well as in the projection, and occasion is thus given for a doubling or double vision. Single vision, in spite of a double pupil, begins in those retinal images in which only the blind spots of the limiting circles of dispersion do not overlap. Patients with double pupils, who have been operated upon, do not see double images of objects if the objects are not very much smaller than the cross-piece which separates the two pupils. From experiments, Schulek concludes that binocular vision, in spite of circles of dispersion upon the retina of one eye, is possible as long as identical points of the retina at least are illuminated by each point of the object. The conditions for binocular single vision would depend, not upon the equal exactness of the retinal images, but upon the fact that identical lines of projection are contained in the sensory impressions of both sides.

PERSISTENT DROPPING OF FLUID FROM THE NOSTRIL ASSOCIATED WITH ATROPHY OF THE OPTIC NERVES AND OTHER BRAIN SYMPTOMS.—Priestley Smith ("Ophth. Rev.," Jan., 1883) reviews several cases of this nature reported by other authors, and gives in detail two cases of his own. The questions which naturally arise in connection with these cases are three: 1. What was the source of the fluid which dropped from the nose? 2. What was the connection between the flux and the brain symptoms? 3. What relation did polypoid growths in the nose bear to the other morbid changes? In view of the fact

that arrest of the dropping was associated in both cases and on many occasions with symptoms strongly suggestive of cerebral compression, it is difficult at first sight to lay aside the hypothesis of an escape of cerebro-spinal fluid; yet this hypothesis appears to be hardly tenable, for in all four of the recorded cases sugar was absent from the fluid. In both of Smith's cases severe brain symptoms, with eventual atrophy of the optic nerves, preceded the onset of the dropping. May not these have been set up by encroachment of a morbid growth upon the upper wall of its containing cavity, as the sphenoid or ethmoid cells—destruction of the bone and inflammation of the meninges. It is not necessary to assume that the growth pressed upon or in any way affected the optic nerves directly; for in one case certainly, and most probably in the other also, the atrophy of the nerves was consecutive to neuritis, and neuritis demands no special locality for the primary lesion. If the bony septum between the nasal cavities and the brain was actually damaged in the way suggested, it is easy to conceive how a stoppage of the downward flow of the fluid through the nostril might lead to pressure on the brain.

THE PATHOLOGICAL TISSUE CHANGES IN SCLERITIS, EPISCLERITIS, AND VERNAL CATARRH.—Ulrich (Ber. d. oph. Ges.; *Beilage* Heft d. "Kl. Mon. f. Aug.," 1882) has found the following microscopical changes in scleritis and episcleritis. The blood-vessels are almost always increased in caliber, their walls thickened, and their lumen filled with blood. In the sheaths and immediate vicinity of the vessels there is an abundant inflammatory infiltration of round cells, so that in preparations colored with hæmatoxylin the sections appear surrounded by a broad layer of blue-colored cells, while the intervening tissue appears normal. In other preparations the conjunctival tissue between the vessels is filled with a more or less marked inflammatory infiltration, which is most marked immediately beneath the epithelial layer. In still other preparations all the layers of conjunctival and episcleral tissue are infiltrated. In some sections were extensive hemorrhages. The main change in the lymphatic vessels was an abnormal dilatation of their caliber, which was most marked in the most superficial conjunctival layers. Only in isolated spots was it possible to demonstrate an endothelial layer. In vernal catarrh of the conjunctiva the changes were mainly in the region of the limbus cornæ. The tissues here were of very firm consistence, and of a pale grayish-red color. The chief change was in the epithelial layer, which was markedly thickened, and the superficial cells were flattened. In the subepithelial conjunctival tissue were found long cone-like or club-shaped prolongations of the epithelial layer. The cells of these structures were of about the same shape, with distinct nucleus, but without any concentric lamination. In some places, in cross-sections of these epithelial prolongations, there were found complete epithelial nests, surrounded by connective tissue stroma, which presented a marked resemblance to canceroid growths in appearance. In some places immediately under the epithelial layer was found that peculiar, bright, homogeneous, glistening layer, which is composed partly of spheroidal, partly of elongated homogeneous masses, and which must be regarded as a conglutinated, albuminous fluid. The connective-tissue stroma of the conjunctiva was in some places entirely unchanged, while in others there was an abundant cellular infiltration and nuclear hyperplasia of the connective-tissue stroma. The tissue was generally but slightly vascular.

BI-ATERAL CENTRAL SCOTOMA: THE COURSE OF THE MACULA FIBERS IN THE OPTIC NERVE, CHIASM, AND OPTIC TRACT.—Vossius ("Arch. f. Ophth.," xxviii, 3) here gives the history in detail of a very interesting case, and from it and other published cases draws the following conclusions: The fibers of the optic nerve which supply the region of the macula lie on the

ventral border of the tract and in the upper and outer quadrant, in two regions separated from each other; in the chiasm they lie close beneath the floor of the recessus opticus, but more in the dorsal half, and run in the intracranial portion of the optic nerves exactly central as far as the optic foramen; from here forward they change their relative position and also the shape of the bundles of fibers. While they before this present a prolate ellipse, in the orbit they present an oblate ellipse, almost a crescentic figure, which immediately behind the optic foramen is situated, not exactly centrally, but more toward the temporal side. Here they remain, finally reach, at the point of entrance of the central vessels into the optic nerve, the temporal side, and run into the papilla almost exactly, in the infero-temporal sector of the optic nerve, in the shape of a wedge, with its base at the edge of the optic nerve, and its edge at the line of the central vessels.

JEQUIRITIC OPHTHALMIA.—WEEKER ("Arch. Ocul.," Nov., Dec., 1882) has employed jequirity in a large number of cases of obstinate granular conjunctivitis, and draws the following conclusions: 1. Lotions of infusion of jequirity seeds produce a purulent ophthalmia of croupous nature, the intensity of which can be regulated by the number of lotions which are employed, and by the strength of the infusion employed. 2. The cornea runs no risk during the evolution of the jequiritic ophthalmia. In only a single case, in which the ophthalmia was pushed to a veritable diphtheritic aspect, was there produced a circumscribed and transient desquamation of the cornea. 3. The jequiritic ophthalmia rapidly cures the granulations, and, even if reproduced several times, it acts with much less danger and discomfort to the patient than inoculation, for it always disappears, without any treatment, by confining the patient for from eight to twelve days in a darkened room.

(To be concluded.)

Letters to the Editor.

THE ACTION OF THE STATE SOCIETY ON THE CODE.

NEW YORK, March 27, 1883.

To the Editor of the *New York Medical Journal*:

SIR: The "Ephemeris" for March, 1883, contains an account of the proceedings of the Medical Society of the State of New York, with reference to the action taken by that body on the question of the code of ethics. The statements of fact therein contained are, in the main, accurate, and the inferences drawn from the facts are mostly warranted by them. In a few points, however, I think the editor of the "Ephemeris" is mistaken. He says: "In receiving communications from county medical societies, four more or less vigorous protests against the action of 1882 were presented from Broome, Madison, Oswego, and Westchester counties, and were referred to the special session for consideration; but neither of these communications received any further attention from the society, either at the special session or at any other time." This is not a fact. The communications referred to were simply ordered on file, from which they might have at any time been taken on motion by the delegates from the counties concerned, or by the leaders of the minority if they had seen fit. That they were not so taken was not the fault of the majority. On the 25th of the "Ephemeris" we find a copy of a resolution, said to have been adopted by the Kings County society, as follows: "Resolved, That this society is in favor of having a code of ethics, and of having one that may be in substantial accord with the principles of the old code of the State society and the present code of the American Medical Association." As much of the present discussion turns on the construction of this, I have referred to the old code to ascertain what might be its principles in this matter. I find, however, nothing expressly defining the qualifications of a person with whom it is proper to consult, except

what may be implied in the following sentence: "All the individuals composing the colleges and medical societies constituted by the Legislature of this State are by them qualified physicians and surgeons." How our friends in Kings County propose to bring this into "substantial accord" with the consultation principles of the American code, I fail to see. It appears to me to be more in accord with the principles of the new code. The editor of the "Ephemeris" complains (page 239) that "the objectors, by skillfully used parliamentary tactics, were able to defeat a vote upon the single simple issue really involved, and which had been alone discussed, and to force a vote upon a confused issue, embracing substitute and supplementary issues never intended to be brought until after the main issue should be decided," etc. As a skillful physician, the leader of the minority surely knows that a delicate stomach will often reject too large or nauseous a dose, which, if administered in divided quantities, will be received and assimilated. As a long-time and experienced member of the State society, he ought to have borne this principle in mind, and have narrowed his resolutions down to the one living issue that was at stake.

On the same page of the "Ephemeris" will be found a paragraph that specially induced the present writer to trouble you with this letter. The paragraph reads (italics my own) as follows: "Immediately after the announcement of the vote, *the successful side of the question* stated that this was only a provisional and temporary settlement of the question, and that next year the question would be brought upon the entire abolition of this new code and of all codes," etc. If it had been stated that a *member* of the successful side, etc., I should have left the statement unchallenged. Surely the editor of the "Ephemeris" must know that many, and I believe the majority, of those who voted for the new code are *not* in favor of the abolition of all codes. It can not be denied, however, that there are in this State really three parties in the field—the old-code, the new-code, and the no-code men. At present the new-code party hold the balance of power, and are in the position of conservatives, lying, as it were, between the extreme radical views of the other two.

Respectfully yours,

H. G. P.

HOSPITAL INSTRUCTION IN NEW ENGLAND.

NEW HAVEN, March 22, 1883.

To the Editor of the New York Medical Journal:

SIR: Allow me to correct an error in your Boston Letter dated February 14, 1883, and published in your issue of February 24, 1883.

After speaking of the hospitals of Boston, the writer says: "So much for the direct neighborhood of Boston. The only other hospitals in New England connected with medical education are those at Portland, Maine, and Burlington, Vermont."

In connection with the medical department of Yale College clinical instruction is given during eight months of each year, both in the amphitheatre and in the wards of the Connecticut General Hospital in New Haven, by four surgeons, two physicians, and one gynecologist, on the subjects of Surgery, Practice, and Diseases of Women.

It is evident that your Boston correspondent does not know all that goes on in the medical world in his native New England, and I doubt not he will thank me for calling his attention to his oversight or lack of information.

I am yours truly,

F. E. BECKWITH,

Yale Medical College.

Miscellany.

DEATH OF DR. WILLIAM H. VAN BUREN.—Although it has been known among Dr. Van Buren's friends for some months past that his health had been seriously crippled by a cerebral affection, rendering it highly improbable that he would ever again be able to resume his professional work, and manifestly threatening the early termination of his life, this premonition, nevertheless, scarcely mitigates the shock felt by the

profession, and by his large circle of personal friends, at the announcement of his death, which took place at his house, in Park Avenue, on Sunday last.

William Holme Van Buren, M.D., LL.D., was born in this city, April 5, 1819. His family is said to have come to this country from Holland in the early part of the preceding century, his great-grandfather having been a pupil of Boerhaave. His grandfather and his father also were physicians. His mother was from Philadelphia. Dr. Van Buren was graduated from Yale College in 1838, and from the Medical Department of the University of Pennsylvania in 1840. After this he spent some time in study abroad, and, on his return to New York, married a daughter of the late Dr. Valentine Mott, and soon took a prominent position as a hospital surgeon, as a teacher of anatomy and surgery, and as a family practitioner. At the time of his death he was consulting surgeon to the New York Hospital, Bellevue Hospital, the Presbyterian Hospital, the Hospital for the Ruptured and Crippled, and the Woman's Hospital, having been an active member of the staffs of the two first-mentioned institutions during the earlier part of his career. He was also a member of the Medical Society of the County of New York, of the Academy of Medicine, of the Society for the Relief of the Widows and Orphans of Medical Men, of the Physicians' Mutual Aid Association, and of the Medical and Surgical Society. For many years he was a professor in the Medical Department of the University of the City of New York, which position he resigned to assume that of Professor of the Principles and Practice of Surgery, and Clinical Surgery, in the faculty of Bellevue Hospital Medical College, a chair that he held up to the time of his death.

Dr. Van Buren was not a copious contributor to medical literature, but yet his name is connected with a number of important and valuable publications, the most notable of his early ventures being a translation of Bernard and Huette's "Précis iconographique de médecine opératoire et d'anatomie chirurgicale," with notes and additions by himself, in conjunction with the late Dr. C. E. Isaacs. During the late civil war he contributed valuable material to the medical and surgical tracts published by the United States Sanitary Commission, a volunteer auxiliary organization to which his counsels were of the greatest aid. But his most memorable literary works, text-books that are destined beyond all peradventure to maintain his impress on American surgery for many years to come, are his "Practical Treatise on the Surgical Diseases of the Genito-Urinary Organs, including Syphilis," written in conjunction with Dr. Edward L. Keyes, and his "Lectures upon Diseases of the Rectum and the Surgery of the Lower Bowel."

As a surgeon, Dr. Van Buren was cool, methodical, and equal to the most trying emergencies; original, suggestive, and thoroughly to be relied on in consultation—a relation in which our best men always esteemed it a pleasure to meet him. As a teacher, he was earnest, dignified, forcible, and graceful. As an author, his charm of style, his just, nay, generous, appreciation of his contemporaries, the pertinence of his statements, and the aptness of his illustrations, made it easy to follow him, and gave the reader the conviction from the outset that his were no idle words. As a family physician, he won not only the admiration but the warm esteem of his patients. As a man, he was honored and loved; no one could know him without these feelings, and even those who met him only casually imbued from him a more favorable estimate of the medical profession than they had before held. Such men the profession can ill afford to spare, and rarely has a funeral cortege comprised more genuine mourners than that which followed Dr. Van Buren's remains from St. Patrick's Cathedral on Wednesday last.

THE LATE DR. GEORGE M. BEARD.—At a meeting of the Medical Society of the County of New York, held on Monday evening, the 26th inst., Dr. A. D. Rockwell presented the following resolutions:

Resolved, That in the death of Dr. George M. Beard this society and the profession at large have lost one of their most brilliant, active, and earnest members. As an investigator, he was original and conscientious. As a friend, he was generous and steadfast. Exposed by his restless activity to many and peculiar attacks, he ever manifested the utmost charity and good humor. Of his worst enemies he seldom spoke a harsh, and never a vindictive word.

Resolved, That to his child and other relatives we tender our heartfelt sympathy.

Resolved, That these resolutions be published in the medical journals of this city.

"In presenting these resolutions," said Dr. Rockwell, "I would simply add that, having been for many years associated with Dr. Beard in a peculiarly close intimacy, it was my fortune to know him, perhaps, better than most others. His self-poise was remarkable. As a foil, so to speak, to the many attacks that followed his original investigations, and his positive and independent methods of expression, he seemed almost to live and move and have his being in humor. His powers were of the most versatile character. His readiness and originality as a scientific writer are well known, but it is not so well understood that he had a genius for an entirely different sort of literary work. While a very young man, serving, during the late war, in the Gulf Squadron, and merely to give vent to his ever-restless mind, he penned a work of fiction which gave evidence of no mean talent in that direction; and since his death an autobiographical sketch has come to light which, for its quaint humor, its keen estimate of character, and its philosophical conclusions, is unsurpassed. I could say much in regard to this individuality, through which ran so rich a vein, and which was in many respects as unique and remarkable as any I have ever known or read of, but I forbear, and content myself with the brief but just tribute embodied in the resolutions."

After brief remarks by Dr. D. B. St. John Roosa and Dr. Wesley M. Carpenter, setting forth Dr. Beard's nobility of character, the resolutions were adopted.

NEW DELEGATES TO THE STATE SOCIETY.—At the same meeting an election was held to fill three vacancies in the society's delegation to the Medical Society of the State of New York, and resulted in the choice of the following-named gentlemen: Dr. Charles A. Leale, Dr. Charles S. Ward, and Dr. Charles Hitchcock. As these gentlemen were nominated and supported by those who favor the restoration of the old code of ethics, their election is a point gained by that party in the profession.

THE CODE OF MEDICAL ETHICS.—This perennial question of medical ethics has received the most considerable agitation for many years, in the late action of the New York Medical Society in reaffirming its position in the matter of meeting practitioners who may have special and peculiar conceptions of the action of medicine. This action is all the more significant from the fact that the indications are that it is intended, by those who took the lead in securing it, to be but preliminary to an attempt, which will be made at the next meeting of the society, to abolish entirely all codical restrictions, thus placing the practice of medicine on the same footing in this regard as all the other callings of men. We believe there is a by no means insignificant number of physicians who regard the code not only as useless, but also as positively narrowing in its influence, and favoring hypocrisy and deceit. These argue that a physician may be a paragon of ethical propriety, and at the same time be guilty of conduct against which the instincts of a gentleman would indignantly rebel. If this be true, wherein lies the value of the code? We venture the statement that of the 75,000 practitioners of medicine of this country, not ten per cent. have ever read the code of ethics of the American Medical Association, and that not five per cent. even of the ethically correct in their deportment toward both the public and their brother practitioners remember enough of it to be of the slightest possible value to them as a guide to conduct. Certain it is that as a guide to the every-day conduct of the physician, it is as if it did not exist. The gentleman does not require it, and he who is not a gentleman can utilize it to cloak his rascality. One of the greatest sticklers for the code whom we know is notoriously unfair toward his brother practitioners, injuring them by innuendo, and robbing them of their patients when he can. Correct medical conduct requires more than can be formulated in words. It requires that rare admixture of regard for others, self-respect, charity, and magnanimity which goes to make up the gentleman. No code can define the constituents of this admixture, and any code which can not define it is useless and in many respects injurious. Better than such a code is the unwritten and indefinable law which defines a gentleman. If physi-

cians were absolved from the obligations of gentlemen and required only not to violate the code of ethics of the American Medical Association, the profession of medicine would soon cease to be the honorable calling that it is.—*Med. Age.*

THE FRUITS OF THE NEW CODE.—Under this heading, a letter signed "Jason" appeared in the "Louisville Medical News" for March 17th: "Since the late meeting of the New York State Medical Society and the adoption of the so-called New Code of Ethics, there is a desire among the members of the profession in this city to obtain a list of the members of the society mentioned who advocated and who approve this departure. It can not be regarded as anything more or less than a desire to affiliate with and encourage quackery, and the authors of the movement should be permitted by reputable members of the profession to enjoy the inconveniences as well as advantages of their chosen position. It is often necessary to refer our friends and patients going eastward to physicians, and it is important to know these members of the New York State Society who have voluntarily severed their connection with the medical profession of the country, so that we may advise accordingly. You will confer a favor upon many of your readers if you will publish the 'black list' in an early number of the 'News.' See my card inclosed herewith."

NEW YORK SPECIALISTS.—After stating that a bill was recently introduced into the New York Senate to prohibit medical societies from adopting rules forbidding practitioners from conferring with others than those of their own school of medicine, the "Medical and Surgical Reporter," of Philadelphia, adds: "This looks like a desperate endeavor on the part of those New York specialists who are itching to consult with all sorts of irregulars in order to increase their income."

WITHDRAWALS FROM A HOMŒOPATHIC SOCIETY.—We are informed that Dr. E. P. Fowler, Dr. J. C. Minor, Dr. Alfred K. Hills, and Dr. Arthur T. Hills have resigned from the Homœopathic Medical Society of the County of New York. Our informant considers this action on their part as foreshadowing their renunciation of sectarianism, a step he thinks they feel encouraged to take by the recent confirmation of the new code.

THE JOHNS HOPKINS MEDICAL SCHOOL.—It is stated that the Medical School of the Johns Hopkins University, in Baltimore, will be opened before the close of the year.

NOTES FROM CHINA.—A correspondent who signs himself "K" writes us as follows: "The Forty-fourth Annual Meeting of the Medical Missionary Society was held in Canton, February 2, 1883, G. Nye, Esq., in the chair. The Hon. Peter Parker, M.D., of Washington, D.C., is president of this society, and the senior vice-president is Prof. S. Wells Williams, LL.D., of New Haven, Conn., both of whom were present at the formation of the society in 1838. The report showed that the aggregate attendance of out-patients was 19,199, and 1,182 in-patients had been treated. The number of surgical operations was 963, of which 47 were lithotomy, 23 lithotripsy, 56 excision of lens for cataract, 74 removal of tumors, etc.

"The cholera prevailed as an epidemic during the summer and autumn months in the Philippine Islands, the island of Hainan (a large island off the southern coast of China), in Cochín China, and Siam. Some cases occurred in Canton, and there may have been cases in the southern part of this province, on the mainland, but it is not known to have existed as an epidemic. The only statistics at hand give the deaths in Manila.

"The total deaths from August 19th to December 12th were 5,413, of which 99 were Europeans; 789 were Chinese; 4,525 were natives; 576 were male children; 411 were female children; 2,088 were male adults; 1,549 were female adults. The greatest mortality was on the 2d of September, when there were 339 deaths.

"A coroner's inquest, protracted through several weeks, has been held in Hong Kong, and excited a great deal of interest. The occasion was the sudden death of one Captain Lee in his berth on board his steamer, which was in dock. Nitrite of amyl was supplied to him by Dr. Fisher, an American doctor practicing in Hong Kong, who hails from the 'University of Fort Wayne, Indiana.' A post-mortem showed extensive disease of both lungs. Dr. Fisher had told him his lungs

were not diseased, and treated him for angina pectoris. After a long examination no definite result was obtained. Grave doubts were left on the public mind as to the skill and judgment of the doctor who holds his degree from the 'University of Fort Wayne.'"

DR. G. H. KIDD, OF DUBLIN.—At the approaching Commencements in the University of Dublin, the honorary degree of *Magister in Arte Obstetrica* will be conferred on Dr. Kidd. This recognition on the part of the Board of Trinity College, of the position Dr. Kidd occupies in that branch of the profession, which his skill and practice have done so much to advance, will meet with the widest approval. Dr. Kidd is Master of the Coombe Lying-in Hospital, and an ex-president of the Royal College of Surgeons in Ireland, and of the Dublin branch.—*Brit. Med. Jour.*

THE YELLOWSTONE PARK MINERAL WATERS.—The "Army and Navy Journal" states that the Secretary of War has sent to the Interior Department a letter from Assistant Surgeon Charles L. Heizmann, U. S. Army, in regard to the medicinal properties of the waters of the mineral springs in the Yellowstone Park, recommending that, in granting leases or franchises to this public domain, the Government should retain the privilege of control over the springs.

ERRATUM.—In Dr. Hopkins's article, in our issue of March 17th, p. 289, first column, fourth line from the bottom, for "supplanted" read *supplemented*.

DEATH OF PROFESSOR VON RINECKER.—Professor von Rinecker, the well-known writer on psychiatry, diseases of children, etc., died recently in Würzburg.

ACTIVE LOCAL TREATMENT IN GLEET.—Dr. J. S. Main writes as follows to the "British Medical Journal": G. B., aged nineteen, intelligent, of strumous temperament, came under my care over twelve months ago, suffering from gleet of five weeks' duration, following upon a sharp attack of gonorrhoea. The discharge was abundant and purulent; the patient himself in a weak condition, and suffering considerably from moral depression. Exploration with a bulbous-pointed catheter enabled me to detect that the raw surface lay just behind the fossa navicularis, and so I thought it a good case for local treatment. Accordingly, having kept the patient in bed, and prepared him by giving, a few hours previously, thirty minims of laudanum, I inserted a medicated urethral bougie containing half a grain of nitrate of silver (the patient having previously emptied his bladder), the orifice of the urethra being kept closed by lateral pressure with the fingers. This "bit" rather severely, and was followed by the symptoms of acute urethritis. After these had passed off, however, I found that the treatment had been effectual, as no symptoms of gleet returned.

I have just lately seen this patient, and he informs me that the cure has been permanent. He mentions, however, that for some months afterward, when he thought "his stomach was out of order," he felt a hot sensation at the part when making water, followed by a sensation of itching. The only other treatment in this case was a tonic of steel and quinine to relieve the depression.

I would remark that, in such cases, unless the patient can be kept in bed for a few days afterward, active local treatment can not be entertained. I have known a case in which acute epididymitis with orchitis (testitis of Bryant) followed the use of a strong injection of sulphate of zinc, the patient being allowed to go about as usual. Supporting the testicles with a suspensory bandage is not sufficient in such cases. In all cases, however, where active local treatment is employed, it is useful, and should not be omitted.

THE OBSTETRICAL SOCIETY OF LONDON.—At the recent annual meeting the following gentlemen were elected officers for 1883: Honorary President, Dr. Arthur Farre; President, Dr. Gervis; Vice-Presidents, Dr. John Brunton, Dr. F. H. Daly, Dr. Clement Godson, Mr. Jonathan Hutchinson, Dr. John Thorburn (Manchester), Mr. J. Lucas Worship (Sevenoaks); Treasurer, Dr. J. B. Potter; Honorary Secretaries, Dr. Galabin, Dr. Herman; Honorary Librarian, Dr. Champneys; other Members of Council, Drs. H. C. Andrews, G. P. Bate, Henry Bennet (Weybridge), P. L. Burchell, T. E. Charles (Cannes), Edward Malins (Birmingham), G. C. P. Murray, W. S. Playfair, George Roper, William

Stephenson (Aberdeen), W. H. Strange, John Wallace (Liverpool), G. E. Yarrow, Sir Joseph Fayrer, and Messrs. Charles J. Cullingworth (Manchester), Alban Doran, Walter Rigden, and John Knoweley Thornton.

BABY-FARMING.—A law lately passed by the Legislature of the State of New York requires persons who board infants to take out a license, and to be subject to inspection by the officers of societies for the prevention of cruelty to children. The power to grant licenses, which are revocable, is given to the Mayor and the Board of Health. Incorporated institutions are excepted from the operation of the law.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 17, 1883, to March 24, 1883.*—MURRAY, ROBERT, Colonel and Assistant Surgeon-General. Detailed as member of Army Retiring Board to convene at the call of the president thereof, at Governor's Island, New York Harbor, for the examination of such officers as may be ordered before it. Par. 2, S. O. 62, A. G. O., March 16, 1883.

SUMMERS, JOHN E., Lieutenant-Colonel and Surgeon. Detailed as member of Army Retiring Board to convene at the call of the president thereof, at Omaha, Nebraska, for the examination of such officers as may be ordered before it. Par. 9, S. O. 62, A. G. O., March 16, 1883.

BILL, JOSEPH H., Major and Surgeon. Detailed as member of Army Retiring Board to convene at the call of the president thereof, at Omaha, Nebraska, for the examination of such officers as may be ordered before it. Par. 9, S. O. 62, A. G. O., March 16, 1883.

IRWIN, B. J. D., Major and Surgeon. Detailed as member of General Court Martial to meet at Whipple Barracks, Prescott, Arizona Territory, April 23, 1883, for trial of Captain J. P. Walker, Third Cavalry. Par. 1, S. O. 62, A. G. O., March 6, 1883.

JANEWAY, JOHN H., Major and Surgeon. Detailed as member of Army Retiring Board to convene at Governor's Island, New York Harbor, for the examination of such officers as may be ordered before it. Par. 2, S. O. 62, A. G. O., March 16, 1883.

BURTON, HENRY G., Captain and Assistant Surgeon. To be relieved from duty in the Department of the East, and will report in person to the commanding general, Department of Dakota, for assignment to duty. Par. 1, S. O. 67, A. G. O., March 22, 1883.

GIRARD, JOSEPH B., Captain and Assistant Surgeon. Detailed as member of General Court Martial to meet at Whipple Barracks, Prescott, Arizona Territory, April 23, 1883, for trial of Captain J. P. Walker, Third Cavalry. Par. 1, S. O. 62, A. G. O., March 16, 1883.

PORTER, JOSEPH Y., Captain and Assistant Surgeon. To be relieved from duty in the Department of the South, and will report in person to the commanding general, Department of Texas, for assignment to duty. Par. 1, S. O. 67, A. G. O., March 22, 1883.

WINNE, CHARLES K., Captain and Assistant Surgeon. Granted leave of absence for three months from March 31, 1883, and will be relieved from duty in the Department of the East, and, upon the expiration of his leave of absence, will report in person to the commanding general, Department of California, for assignment to duty. S. O. 61, A. G. O., March 15, 1883.

NAVAL INTELLIGENCE.—Passed Assistant Surgeon Nelson McP. Ferebee has reported for duty at the Norfolk Navy Yard. Passed Assistant Surgeon Magruder, now on special duty at Ville Franche, has been ordered to proceed at once to Malta, to render personal attention to Commander Dewey, who is sick at the English Hospital there.

It is said that the death of Mrs. Heneberger, the wife of Passed Assistant Surgeon L. G. Heneberger, was due to a subcutaneous injection of two drachms of [?] a solution of [?] morphine, used by mistake instead of carbolic acid. Surgeon John H. Clark has been ordered to hold himself in readiness for sea service on being relieved as a member of the Medical Board. At the Naval Hospital and the Naval Laboratory, Brooklyn, Dr. Bloodgood, now in charge of the hospital, succeeds Dr. Cones at the laboratory, and is relieved at the hospital by Medical Director Richard C. Deane, now on duty in Philadelphia.

Assistant Surgeon James D. Gatewood acted as judge advocate at a summary court-martial lately convened on board the New Hampshire at Newport. We are indebted to the "Army and Navy Journal" for the foregoing items.

Lectures and Addresses.

LECTURES ON HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., ETC.

LECTURE III.

(Concluded from page 312.)

I pass now to another set of cases—the secondarily automatic actions performed during profound sleep. I remember when my friend, Sir James Fitz James Stephen, now one of our most distinguished judges, came home from India, whither he had been sent as the legislative member of the council, he told me, in speaking of this subject, that he had noticed that the punkah-pullers would go on just as well during sleep as when awake. (I suppose I need hardly tell you that a punkah is a frame suspended from the ceiling by hinges or cords, with a large piece of linen or muslin stretching across it—in fact, a fan upon a gigantic scale—which is pulled backward and forward by a string from the outside of the room, for hours together, over the head of any one who wishes to enjoy the movement of air produced by it.) “But,” added my friend, “you must consider that these punkah-pullers have probably been exercising their vocation hereditarily for some thousands of years,” which is no doubt the case, because (as you know) everything in India goes by *caste*; and there is a caste of punkah-pullers just as there is a caste of cooks, or a caste of weavers. And in regard to this last-named caste, it occurs to me to suggest whether the extraordinary manual skill of the spinners and weavers of those wonderfully fine Daeca muslins that are sometimes called “woven air” is not partly the result of an hereditary capacity for its acquirement, originally developed and improved by habitual training, and ultimately becoming embodied (as it were) in their physical constitution.

Before proceeding to consider how the will originally shapes that mechanism, I shall call your attention to some other forms of secondarily automatic action, in which we have combinations of a more complex kind, that can only be made under the guidance of sensations.

Let us take, in the first place, the act of speech. The learning to talk, as you must have all observed, is usually, in the first place, a very slow process on the part of the infant. We occasionally, it is true, meet with instances in which it seems to have been more rapid, the child having gone on to three years of age, or even more, scarcely uttering a dozen words, but obviously understanding all that was said, and at last coming out with articulate speech of a very complete kind—not the ordinary infantile speech, but the speech of a grown child. But in these cases there has been really a long training, for the child has been storing up these impressions of the words *as heard*, which become his guide in the future utterance of them; and, by the acquirement of even a small number of spoken words, he has brought the apparatus into working order, so as to be able to give expression to the conceptions he has mentally formulated. In this respect, the

child who talks late has a decided advantage over the one who begins much earlier, for it is clear, in regard to the latter, that the guidance of recollected impressions is much less distinct.

Now, articulate speech involves two distinct classes of actions—the production of vocal tones by the laryngeal apparatus, and the shaping these tones into words by the movements of the tongue, lips, and other organs of articulation. Both these kinds of action are differentiated from our ordinary muscular movements in this, that they are normally guided, not by the “muscular sense,” which enables us to appreciate the degree of tension or strain that we are calling upon the muscles to exert, but by the sounds which the vocal apparatus gives forth; that is, by the auditory impressions we receive through our ears. This is the case equally in the production of vocal tones by the action of the laryngeal muscles (in conjunction with the muscles of expiration), and in the modification of those tones by the muscles of articulation.

And it is equally, and even more remarkably, the case in the production of musical tones in singing, the pitch of these tones depending upon the tension of the vocal cords, which has to be regulated with the most extraordinary precision by the action of the laryngeal muscles, in order that we may sing “in tune.” To do this, you must first have a distinct conception of the tone to be uttered; and, if your hearing tells you that you are not sounding it correctly, you strive to bring it into accord, either with your own conception, or with the voice or instrument which is accompanying you. When a singer does not keep good tune (I have known this the case with admirable and highly trained voices), the fault is commonly attributed to a “bad ear.” But this is not usually the case. The source of it lies in imperfect control over the mechanism of vocalization, which is very often the consequence of emotional disturbance. The singer knows well that he (or she) is singing woefully out of tune, and yet feels powerless to get right until (it may be) the trouble is forgotten in the interest of the music, or the dramatic singer “warms” to his performance.*

Every one knows that a child born perfectly deaf (or “deaf-mute”) can not learn speech in the ordinary way; and that, if left to itself, it will never acquire the power of vocalization. Its only vocal utterance is a mere inarticulate cry, which it does not itself hear, and which is the expression of its emotions, not of any intellectual condition. But by taking advantage of another class of sensations—those received through the “muscular sense” of the vocal muscles themselves—and, by a very careful and difficult process of training based on these, the deaf-mute may be taught to speak articulately. The mode in which this is brought about is elucidated in a very interesting way by the recorded experience of a man of whom many of you have doubtless heard—the late Dr. Kitto, a biblical scholar of considerable eminence, who was held in high estimation in England for his knowledge of eastern languages, life, and usages, which he had acquired by study and travel.

* I well remember this to have been the case with two of the finest vocalists of my earlier days, Mrs. Alfred Shaw and Reneon.

Dr. Kitto, in a little book called "The Lost Senses" (which he wrote at the request of Mr. Charles Knight, a well-known publisher in London), recorded the facts of his early life briefly in this form: He was a peasant lad, his father being an ordinary day laborer, and had been brought up with scarcely any school instruction or early training. He was not born deaf, but became so by accident. When he was about nine years old he fell from the roof of a house he was thatching, and was taken up perfectly insensible. I gather, from the details which he gives, that there was most probably a fracture across the base of his skull, which completely ruptured the two nerves of hearing, tearing them through in a way which prevented their ever reuniting. From that time he was as perfectly deaf as any one born in that condition, the loss of his sense of hearing being more complete than I have known it to be in the case of any other person who has once heard. He lay for, I think, ten days in a state of insensibility; and then, when he began to recover, this deafness soon made itself felt, for he could not hear any sound whatever. He goes on to tell that he very soon began to give up speaking, for he felt the attempt to speak gave him a painful feeling in his throat. I believe the meaning of this to have been, that, having lost the guiding sensation of sound, he had to fall back upon the muscular sensations originating in the muscles themselves—sensations which we entirely disregard in our usual state when we are under the guidance of our hearing; and that the discomfort was due to the intensification of these sensations by the attention he gave them while endeavoring to regulate his speech by the indications they furnished him. It was sufficient to cause him to give up all attempts to speak for many years.

I may give you a means of testing for yourselves the effect of this kind of substitution. The movements of our eyes are ordinarily guided by the visual sense instead of by the muscular sense of the muscles themselves; but if you will go with your eyes open into a room that is *perfectly* dark, or in a room which is partly light, will not only close your eyes but completely cover them up by your hands, so as to let in no light whatever from the outside, you will find that, if you try to move your eyes upward, downward, or to either side, you will have a very uncomfortable feeling of tension in the muscles of your eyes. And every ophthalmic surgeon knows how difficult it often is, in cases of such total blindness that even light is not distinguished, to get the patient to move his eyes in any given direction. He has not the ordinary guiding sensation, and has not learned to adapt himself to any other. This was, I think, young Kitto's condition when he first lost his hearing. He continued in this condition for several years, applying himself to literary study, in which he succeeded so well as to obtain much notice in his rural neighborhood. It then came about that he was taken out to the East by some kind missionaries, who, finding that he had once known how to speak, refused to hold converse with him by his slate. They told him that he ought to put himself as much as possible in the condition of other persons, and that the kindest thing that they could do was to make him speak; and gradually he acquired the power of vocalization again, and could get on in very much the same way as regards speech that the deaf mutes do. These, as you know, are

now very commonly taught to speak by a systematic process of training. The first thing to be done in teaching a deaf-mute to speak is to get the child to utter a vocal tone. You have, I dare say, formerly heard deaf-mutes trained on the old method—speaking in a kind of hoarse whisper, having been taught to articulate, but not to produce a real voice. The way in which this is now done (at least in which I have myself seen it done, which I suppose to be the usual method) is to place the child's finger upon the larynx of the teacher, who then utters a vocal tone; and the child feels the thrill or vibration that the utterance of that tone produces. The child's finger is then placed upon its own larynx, and it is encouraged to go on making efforts, until it feels the corresponding thrill in itself; and, once the vocal tone is brought out in that manner, the child can reproduce it after a time by his own will. This becomes the basis of all further training, the conversion of this vocal tone into articulate speech being effected by movements which the pupil can be taught to imitate by seeing them executed by his teacher.

Here, then, we see exactly the same process as is followed in any other training for the performance of one of the secondary automatic movements we have been considering, viz.: the direction of the attention to the act, in the first instance, and then the calling forth of the effort to imitate it. Look at the child learning to walk. You recognize at once the expression of feeling which the child has of the want of balance, and which is itself the result of the attention it gives to the indications of the muscular sense; and, by continued attention to this, the child is gradually taught to perceive that by calling certain muscles into action it can maintain its balance. The training is precisely the same that the rope-dancer has to go through to walk on a rope or a wire, only that in the infant it is given by another whose help is always ready to prevent injury and remove the feeling of alarm which interferes with the automatic regulation; while the rope-dancer volitionally trains himself to bring the balancing apparatus of his body to work automatically in accordance with the communications it receives through the organs of sense.

Now, I believe the same to be the case even with our (so called) voluntary acts, for each of us has first to train his automaton to do the work which he desires to execute. Take the act of writing or of drawing, billiard playing, or music playing of any kind, or any skilled artisan work; I need not tell you that, however strongly we may *will* to perform either of them, we can not do so without *practice*. We must *learn* to do it; and the "learning" consists in the shaping of our automatic mechanism to the particular kind of action, and so bringing it under the control of the will as readily to execute its behests—the Cerebrum saying to the Axial Cord (if I may use the metaphor), "Do this," and the Axial Cord obediently doing it *for* us, not *by* us. You have heard of the sailor who was asked if he could play the fiddle, and who said, "Well, he didn't know, he couldn't tell till he tried." You all know what would happen if he did try. He might be musician enough to be able to read music perfectly, so as to know the import of every note and interval, and thus to study the violin-part mentally; he might know, too, how the violin is tuned, and what are the notes which every string will give according to the manner in which it

is "stopped"; he might have mastered, theoretically, the mode in which his fingers should be placed to bring out each note of every string; and yet you know perfectly well how utterly powerless he would be to play the violin until he had *practiced* it. Such practice consists in bringing the movements of the hand into direct response to the impressions received through the eye, the ear, and the muscular sense, and to the mental conception of the sounds he desires to evoke. The automatic mechanism of the accomplished violin-player becomes capable of executing without difficulty any music (suitable for the instrument) which his eye can read, or his ear hear, or his imagination conceive, his will simply directing it (like the "conductor" of an orchestra) and fixing the attention, where necessary, on the *nuances* which require particular expression. And the same is the case, of course, with performance on any other musical instrument. Now, see what may happen to a musician thus trained, in playing a piece which, though it may be really very difficult, he has so thoroughly mastered by practice that its performance has become easy to him, the mechanism to execute it having, so to speak, been constructed in his organism.

I dare say that every lady or gentleman in this hall who may be a performer on any musical instrument knows perfectly well that a piece may be played, and played correctly, in good time, the *pianos* and *fortes* well observed, and with appropriate "expression," when called for, while the *mind* of the performer is engaged upon some subject altogether different. Many a young lady has been known to go through a "piece," when called upon to "play," with her thoughts and feelings entirely engrossed upon her own love affairs, or some other interesting subject, and has said to her confidential friend at the end of it, "I really wonder how I could have got through it."

I can give you another very curious illustration of this independent action of the trained mechanism, as shown in the performance of a very similar exercise under extremely peculiar circumstances. Some of you may have heard, in days long past, a very successful London entertainer, Albert Smith, who gave a humorous recitation, occupying about an hour, descriptive of the Overland Route (when that was a novelty), afterward of an ascent of Mont Blanc, always including a very amusing "patter song," as it is called, which he sung to his own accompaniment on the piano, bringing in any topic of the day. Albert Smith went through this entertainment day after day, occasionally varying it a little by the introduction of a new verse into the song, many thousands of times, and his performance of it had come to be so completely automatic that, on one occasion, having received, immediately before its commencement, a letter informing him that a firm had failed in which he had invested a very large sum of money, nearly the whole of his savings (he was a careful man, and not at all of the reckless type), he went through it as usual, though he afterward said that he had not the slightest recollection of anything but the intelligence he had just received, which kept complete possession of his thoughts during the whole performance. According to my view, Albert Smith's cerebrum and his automatic apparatus were *functionally* dis severed in this condition, each going on

with its own work independently of the other. And, however incredible it may seem to a metaphysician that a train of action which he would regard as essentially *mental* could be kept up by a bodily mechanism, the only alternative lies in the hypothesis of two distinct personalities—one, Albert Smith thinking about the loss of his money, and the other giving his mind to his performance. This is so manifestly absurd that I feel sure you will agree with me in regarding the performance as the expression, not of Albert Smith's *then* mind, but of his *former* mind, which had so completely impressed itself upon his automatic mechanism by multitudinous repetitions of the same series of acts that the latter, when once started, could go on of itself to the completion of it. And I shall now give you a very curious example of this independent action in another kind of performance, viz., music playing.

Since the publication of my views on this subject, I have received many valuable communications in relation to it; and among them one from a clergyman in Yorkshire, narrating an experience of his own, which he thought would interest me; and I present it to you nearly in his own words. When a student at Trinity College, Dublin, my informant was one evening at a party, at which, after supper, the young people thought they would like to have a dance. A lady who was there, the wife of a surgeon in the army, was asked to the piano, it being known that she could play dance-music of any kind from memory with great facility. Soon after she sat down to the instrument, however, it appeared that she had taken too much wine at supper, for her eyelids dropped, her head fell forward, and she showed every sign of sleep except snoring, being, in fact, so drunk as to be totally unable to rise from her music-stool. Yet she went on continuously with the quadrille she was playing, keeping the time perfectly, and the only difficulty was to stop her when the dance was over. If she was then awakened sufficiently to make her understand what was next wanted, and her hands were placed on the keys, she would start off afresh, soon relapsing into profound sleep, but continuing to play well—her automatic performance going on until it was again stopped.

This case will, I think, satisfy you that not only long successions of similar movements (as in walking), but successions of dissimilar movements, if linked together by frequent repetition, may be performed without any other act of the will than what is needed to set them going.

The process by which our automatic mechanism constructs itself, so as to reproduce by its own independent activity the sequences it has been trained to execute, finds a curious parallel in Edison's phonograph. You know that if you speak into the mouth-piece of this apparatus while its barrel turns, the vibrations produced in its metallic disc by the vocal sounds so impress themselves on the smooth surface of the revolving barrel that when, by shifting the barrel, these indentations are caused to pass in succession under the point that made them, they reproduce, by its connection with the disc, the vibrations originally given to it by the voice, and cause it to utter articulate sounds bearing a more or less close resemblance to the words that had been spoken into the mouth-piece. And it is quite conceivable that, by an appropriate mechanism attached to an organ, a player could so

indent the surface of a revolving barrel that every note he has caused the pipes to utter should be accurately recorded, so that the subsequent turning of the barrel should cause the instrument to reproduce them in their exact sequences and combinations. I think you will agree with me that, in the case I last cited, the performer was just as much an automaton as a musical box or mechanical organ, which thus gives forth the tunes set on its barrel. And the only difference that I can see between her condition and that of a practiced musician who goes through a similar performance wide awake, but thinking of something else all the time, is that the latter has it in his own power to go on or to stop playing, his cerebrum, instead of being altogether inactive, being otherwise engaged, but being accessible to any intimations that may call into exercise his control over his automatic mechanism.

This last condition is so common—I might say, so universal—as regards the act of walking, that I can scarcely doubt its having fallen within the personal experience of every one present. Nothing is more common than the continuance of the regularly alternating movements of the legs while the attention is uninterruptedly fixed either on a train of thought which occupies the mind of the subject, or on the maintenance of a close conversation with a companion. I remember to have heard from John Stuart Mill that he thus thought out his “System of Logic” during his daily walks between his residence and the India House, trusting to his automatism to transport him from one to the other, according to the direction it had habitually received. Yet if any unusual occurrence had interrupted his cogitations, and called his attention to his “environment,” his cerebrum would have resumed its control over his automaton, and adapted its action to whatever new requirement might have arisen.

I shall add one more illustration, which, I think, will interest you. Among other communications I have received on this subject were some from telegraph clerks, who told me that they could transmit a message—taking in its words by their vision, translating these (as it were) into telegraphic signs, and manually communicating these signs to the telegraph-instrument—without *thinking* about the message, or even apprehending its meaning, their minds being entirely occupied by their own thoughts. And one of my informants went so far as to say that he thought he did his work better in that condition than when his mind was consciously given to it, finding himself less likely to make mistakes when he left his automaton to do it for him than when he gave his attention to its working. Another assured me that he was quite certain he had not only himself telegraphed messages in his sleep, but that he had seen other clerks do it. I do not think that this statement is at all more incredible than the case of the lady piano-forte player I have already cited; because we know that the eyes may be open to receive and transmit visual impressions, when the *consciousness* of these impressions in the receiving center is suspended in sleep. And I do not see any difficulty in supposing that the impressions so made on the receiving organ, which has been trained to respond to them automatically, may excite the respondent movements, even without that consciousness

of the impressions in which *sight* consists. I do not say that I consider the fact to be proved, because I think that my informant may possibly have deceived himself. But I submit it to you as a reasonable probability which accords with other experiences of the same class.

I wish to say a few words in conclusion with respect to a series of phenomena which I think important to the full understanding of this automatism, though they are not normal, but morbid. They are forms of reflex activity which are called forth through the axial cord, and may be produced either by some over-excitability in the central organ to ordinary stimuli, or by some abnormal excess of stimulation, originating in the parts from which the stimulus is conveyed to the centers. You have all heard of the state called *tetanus*, commonly called “lock-jaw”; lock-jaw, however, being only one form of the tetanic convulsion. This condition is sometimes the result of the administration of a poison—strychnine, for example—which produces an excessive excitability of the spinal cord, the upward prolongation of which forming that higher part of the axial cord which lies within the skull, and constitutes the ganglionic center of the special senses, not being affected. A similar excitability occasionally arises spontaneously from some morbid process dependent on local injury; and the fatal termination of the tetanic convulsion is generally the result of the spasmodic fixation of the respiratory muscles. But in hydrophobia a somewhat similar convulsive action is occasioned by the peculiarly excitable condition of the upper part of the axial cord, the impressions received through the special senses being very apt to call it forth. This, as is well known, is peculiarly the case with the *sight* or the *sound* of water; but it is a very noteworthy fact that the sight of a *picture* of waters, or even the verbal suggestion of the *idea* of waters, will often call forth the hydrophobic spasm. This presents us with the analogue in disease of what I have already pointed out to you in regard to the ordinary act of coughing—namely, that the same automatic action of the axial cord may be called forth either by an impression transmitted to it through some afferent nerve, or by a mandate sent down to it from the cerebrum. Thus, in the hydrophobic condition, the ideational state produced either by the verbal suggestion of water, or by a picture of water, operates in exactly the same way as the excitant of the terrible spasm, as do the actual sight and sound of water called up by sense-impressions received from the eye or the ear.

Another example of the reflex character of these convulsions is presented by a form of disease which many of you have perhaps unhappily witnessed—the teething convulsion or spasmodic croup of infants. The stimulus which excites this convulsion is given by the pressure of the advancing tooth against the capsule which it is trying to break through; and the convulsive attack is often relieved for a time by lancing the gum. But the condition of the nerve-centers which makes that irritation call forth the spasm is very often due to bad air or bad food; and thus, as I have often seen, change of air may immediately remove the tendency to this convulsion which had previously shown itself with the advance of every tooth.

There is one more action that we scarcely term abnormal

—one which affords a singularly good illustration of the view which I have been endeavoring to impress upon you; the act of yawning is essentially a respiratory movement, and naturally arises in this way. We have been sitting with our attention fixed—I dare say that some of you feel a strong tendency to it at this moment—during an hour's lecture, it may be; our ordinary respiratory movements have been restrained; we have not, as we usually do when at ease and liberty, taken every now and then a longer and fuller inspiration than usual, which clears the chest of any excess of foul air that may have remained in it; and we accordingly feel a discomfort resulting from its accumulation. Thus is called forth a peculiarly long inspiration, attended with a wide gaping of the mouth. But this movement may also be called forth by what we call imitation; the sight or the sound of one person's yawn often produces the yawn in another. There used to be a story current in Glasgow, many years ago, of a professor who unfortunately dislocated his lower jaw whenever he gaped very wide; and the joke used to be that, when the students were tired of his lecture, they would get up a yawn among themselves, which would go round the class and be then caught by the professor, who would thus be forced, not to "shut up," but to remain with his mouth wide open until the dislocation of his jaw could be reduced. I have been told—I have never tried it myself—that a movement of like kind made with the hand, or with a pair of tongs, will generally produce the effect. And some of you may now be experiencing that the mental suggestion I have given is strongly exciting a disposition to the act, which is only to be restrained by a determinate effort of will.

Notwithstanding the familiarity of these facts, I regard them as having a very striking significance.

In the first place, they show the origination of the act to arise out of the primary organization of the nerve-center of the normal respiratory movements, in virtue of which this occasional exaggeration of them is called forth automatically, so as to obtain a more thorough aëration of the blood that circulates through it; and of this we have the best evidence in the fact that yawning-fits are very frequent in infants and young children, who have no motive for suppressing the tendency. But the centric predisposition to the act may not be strong enough to call it forth spontaneously, and may yet be sufficient to give effect to some external stimulus; and thus we see that, under such circumstances, either the sight or sound of the act in another, or the mental suggestion of it (such as I myself feel at this moment), calls forth a tendency to it. And even when, the blood being thoroughly aërated, the centric predisposition is wanting, a repetition of such stimulus and the direction of the attention to it will often prove almost irresistible.* Lastly, we have here, as in many other cases of automatism, an example of the controlling power of the will when exerted in opposition to the respiratory impulse; for, when we have a strong reason to wish to suppress a yawn, we can generally do so by put-

ting the will in force through the cerebrum, so as to antagonize the automatic mechanism.

I have now completed that general survey of the automatism of the human body which it has been my object to place before you, and in the next lecture I shall proceed to that of our mental action.

MEDICAL ETHICS AND ETIQUETTE.

COMMENTARIES ON THE NATIONAL CODE OF ETHICS.

By AUSTIN FLINT, M. D.

Fourth Article.

OF THE DUTIES OF PHYSICIANS TO EACH OTHER AND TO THE PROFESSION AT LARGE.

ART. I.—*Duties for the Support of Professional Character.*

SECTION 1. Every individual, on entering the profession, as he becomes thereby entitled to all its privileges and immunities, incurs an obligation to exert his best abilities to maintain its dignity and honor, to exalt its standing, and to extend the bounds of its usefulness. He should, therefore, observe strictly such laws as are instituted for the government of its members; should avoid all contumelious and sarcastic remarks relative to the faculty as a body; and, while by unwearied diligence he resorts to every honorable means of enriching the science, he should entertain a due respect for his seniors, who have, by their labors, brought it to the elevated condition in which he finds it.

SECTION 2. There is no profession from the members of which greater purity of character and a higher standard of moral excellence are required than the medical; and to attain such eminence is a duty every physician owes alike to his profession and to his patients. It is due to the latter, as without it he can not command their respect and confidence, and to both, because no scientific attainments can compensate for want of correct moral principles. It is also incumbent upon the faculty to be temperate in all things, for the practice of physic requires the unremitting exercise of a clear and vigorous understanding; and, on emergencies, for which no professional man should be unprepared, a steady hand, an acute eye, and an unclouded head may be essential to the well-being, and even to the life, of a fellow-creature.

SECTION 3. It is derogatory to the dignity of the profession to resort to public advertisements, or private cards, or handbills, inviting the attention of individuals affected with particular diseases—publicly offering advice and medicine to the poor gratis, or promising radical cures; or to publish cases and operations in the daily prints, or suffer such publications to be made; to invite laymen to be present at operations, to boast of cures and remedies, to adduce certificates of skill and success, or to perform any other similar acts. These are the ordinary practices of empirics, and are highly reprehensible in a regular physician.

SECTION 4. Equally derogatory to professional character is it for a physician to hold a patent for any surgical instrument or medicine; or to dispense a secret nostrum, whether it be the composition or exclusive property of himself or of others. For, if such nostrum be of real efficacy, any concealment regarding it is inconsistent with beneficence and professional liberality.

* The lower jaw is often depressed in yawning farther than it can be by voluntary effort; so that, when I have suggested a yawn to myself by a voluntary gape, I have found the gape extended involuntarily.

and if mystery alone give it value and importance, such craft implies either disgraceful ignorance or fraudulent avarice. It is also reprehensible for physicians to give certificates attesting the efficacy of patent or secret medicines, or in any way to promote the use of them.

The late Alexander H. Stevens, in his acknowledgment of the honor of an election to the presidency of the American Medical Association, at its first annual meeting in 1848, spoke of the profession of medicine in the following terms: "Our profession, gentlemen, is the link that unites Science and Philanthropy. It is one of the strongest ligaments that binds together the elements of society. It teaches the rich their dependence, and elevates the poor to a sense of the innate dignity of their nature. Its aim is to add to the comfort and duration of human life. In a country where population is not crowding on the means of subsistence, and where every individual has the largest opportunity of promoting his own happiness and of perpetuating it in his posterity, the medical profession, entirely philanthropic in its objects, more intimately connected with the pursuits of science than the other learned professions, and not overshadowed by an hereditary aristocracy, enjoys pre-eminently a high social position, and, for all legitimate objects, a commensurate influence." Eulogiums equally glowing, in view of its beneficent objects, have come from speakers and writers not of the medical profession. It is not a small thing to belong to a profession so much honored, and plainly it is the duty of its members to do nothing to impair, but everything to sustain and promote, its honorable character. It may be said that the sentiments expressed in relation to the "duties for the support of professional character," contained in the two first sections under this head, are mere truisms and platitudes. This may be said with regard to any collection of ethical principles for the regulation of human conduct. Experience shows the importance of the embodiment in language of moral principles pertaining to other of the relations of life, and there is reason to believe that this portion of the code has had not an inconsiderable influence upon the character of the profession by inciting its members to become worthy of it, and to render it still more worthy of the estimation in which it is generally held by the public.

There can be no difference of opinion in the minds of worthy physicians as to the acts which in the third section of this article are specified as derogatory to the dignity of the profession. But the propriety of the interdiction of these acts by the code is not always appreciated by the public. As a reason for their being interdicted as "highly reprehensible in a regular physician," it suffices to say that "they are the ordinary practices of empirics." The public should understand that these practices are criteria of irregular or unworthy practitioners. With this understanding, if persons consent to be influenced by such acts, the responsibility for consequences lies with themselves. The credulity in regard to therapeutics which is inherent in the minds of many will doubtless always afford encouragement for a continuance of the various meretricious methods of obtaining credit for superior medical or surgical skill.

There are certain conventional rules, differing in differ-

ent places, which come under the head of etiquette rather than ethics. In the city of New York it would be deemed unbecoming to insert a card with residence and office hours, or a notice of removal, in a medical journal, and still more in a newspaper or any non-medical periodical. But in some other cities such notices in a medical journal are not looked upon as improper, and in some parts of the country even advertisements in newspapers by physicians, stating that they are candidates for practice, are not objected to. In Paris a professional door-plate is a deviation from propriety. In New York a door-plate or sign, modest in its proportions as in other regards, is the rule. But in some places the traditional "doctor's shingle" is a board which, in size and conspicuousness, would answer for a drug-shop, with, perhaps, an arrangement for illumination at night. In these and other matters falling in the category of conventional rules, it is, to say the least, not in good taste for any one to go beyond the limits which custom defines.

The grounds for the injunction not to patent remedies or surgical instruments, and not to dispense secret nostrums, are not always appreciated by the public. Some appear to think that it is dictated by jealousy or professional prejudice. The reasons are concisely but clearly stated in the code. Imagine Jenner to have applied for a patent giving exclusive property in vaccination, or keeping it a secret! How different would the names of those identified with the discovery and introduction of anaesthesia in surgical and medical practice appear in history had the attempt not been made to withhold from the profession and the public the agent employed, and to secure a proprietary interest therein! Here, as in all other instances, the restrictions of the code of ethics have reference to the welfare of the community, and not to the selfish interests of the medical profession.

ART. II.—*Professional Services of Physicians to each other.*

SECTION 1. All practitioners of medicine, their wives, and their children while under the paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them, whose assistance may be desired. A physician afflicted with disease is usually an incompetent judge of his own case; and the natural anxiety and solicitude which he experiences at the sickness of a wife, a child, or any one who, by the ties of consanguinity, is rendered peculiarly dear to him, tend to obscure his judgment, and produce timidity and irresolution in his practice. Under such circumstances, medical men are peculiarly dependent upon each other, and kind offices and professional aid should always be cheerfully and gratuitously afforded. Visits ought not, however, to be obtruded officiously, as such unasked civility may give rise to embarrassment, or interfere with that choice on which confidence depends. But if a distant member of the faculty, whose circumstances are affluent, request attendance, and an honorarium be offered, it should not be declined; for no pecuniary obligation ought to be imposed which the party receiving it would wish not to incur.

Proper delicacy as regards visiting their brethren in sickness is not always observed by medical men. From the best of motives, the professional friends and neighbors of a sick physician are apt to call upon him, inquire into his case, proffering their opinions and advice, without any concert between them, and the result is that a medical patient

may receive no systematic treatment; he is more poorly cared for in this respect than the poorest of non-medical patients. He often can not, without much embarrassment, exercise the privilege of the latter in selecting the advisers whom he would prefer. He should not be deprived of this privilege, and the greatest care should be taken to secure it for him. Except in cases where close intimacy dictates a deviation from the rule, a physician should not ask to see another physician in illness until requested to do so. The manifestation of interest and sympathy should be limited to kind messages and inquiries through others. It is as important to a physician who is sick as to others, to have a regularly selected physician in attendance, and consultations, if desired, should be had in the same way as in other cases.

Naturally and properly, medical services rendered to members of the profession should be gratuitous. The rule with regard to an honorarium, however, is a sound one in this application: namely, one has no right to impose a pecuniary obligation when it is distinctly against the wishes of the party receiving the services. This rule is applicable here as in other cases. A request to present a bill for services, however, should never be made. Such a request implies an expectation that it will not be complied with. Any pecuniary acknowledgment by a member of the profession for medical services should be made strictly as an honorarium.

ART. III.—*Of the Duties of Physicians as respects Vicarious Offices.*

SECTION 1. The affairs of life, the pursuit of health, and the various accidents and contingencies to which a medical man is peculiarly exposed, sometimes require him temporarily to withdraw from his duties to his patients, and to request some of his professional brethren to officiate for him. Compliance with this request is an act of courtesy, which should always be performed with the utmost consideration for the interest and character of the family physician, and, when exercised for a short period, all the pecuniary obligations for such service should be awarded to him. But if a member of the profession neglect his business in quest of pleasure and amusement, he can not be considered as entitled to the advantages of the frequent and long-continued exercise of this fraternal courtesy without awarding to the physician who officiates the fees arising from the discharge of his professional duties.

In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety, and responsibility, it is just that the fees accruing therefrom should be awarded to the physician who officiates.

The code of ethics defines the line of conduct in many instances of which it may be said that a proper courtesy and sense of honor should suffice without formal ethical rules. Assuming that an adequate degree of courtesy and sense of honor belong to members of the medical profession in general, to assume this for all members would be to claim for medicine, in a moral point of view, a position far above that of any other pursuit. Ethical rules, therefore, are needed for a greater or less number of physicians. But, irrespective of any question of moral delinquency, rules are useful by indicating precisely what is to be done under certain circumstances, thus preventing embarrassment and saving the

trouble of discussion in particular instances. It is to some extent a popular impression that the feelings of physicians toward each other are rather repellent than attractive. This impression is groundless. There is no class of men among whom fraternal sentiments prevail more than among practitioners of medicine. Personal antipathies from local jealousies, and, occasionally, incident to differences in opinion concerning questions which are considered as involving important interests of the profession, do not invalidate the correctness of this statement. Requests for vicarious offices, as well as other services for professional brethren, are usually cheerfully complied with.

Vicarious offices offer an opportunity for one deficient in a proper sense of honor to undermine the confidence of patients in their physicians. This may be done, not openly, but insidiously, by questions, expressions of surprise, over-assiduous attentions, etc. It will do much toward neutralizing such violations of honor if the public be made acquainted with the article of the code which relates to these offices. Patients will be led to understand the motive which prompts such dishonorable efforts, and, so far from accomplishing the objects, they will justly react upon unworthy members who act in opposition to the spirit of the code. It sometimes happens that a patient placed under the care, temporarily, of a practitioner, prefers that the substitute should continue permanently in charge. A patient may express a wish to that effect from a feeling that it is an act of courtesy to do so, at the same time, perhaps, being anxious that the family physician should resume his services. In order to avoid all difficulties, the physician who has performed vicarious offices in any case should relinquish the case, as soon as these offices are no longer needed, into the hands of the physician for whom he has acted, without any explanation or discussion with the patient or friends. If requested to remain in charge, he should positively decline. The family physician, after having been reinstated, is then, of course, free to act in conjunction with the wishes of the patient and friends, as regards the continued attendance of his substitute, either in consultation or in charge of the case.

The rules in regard to fees being clearly stated, there need be no embarrassment nor discussion on this score in particular cases.

ART. IV.—*Of the Duties of Physicians in Regard to Consultations.*

SECTION 1. A regular medical education furnishes the only presumptive evidence of professional abilities and acquirements, and ought to be the only acknowledged right of a man to the exercise and honors of his profession. Nevertheless, as in consultations the good of the patient is the sole object in view, and this is often dependent on personal confidence, no intelligent regular practitioner, who has a license to practice from some medical board of known and acknowledged respectability, recognized by this association, and who is in good moral and professional standing in the place in which he resides, should be fastidiously excluded from fellowship, or his aid refused in consultation, when it is requested by the patient. But no one can be considered as a regular practitioner or a fit associate in consultation whose practice is based on an exclusive dependence on the rejection of the accumulated experience of the profession, and

of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry.

The foregoing section has of late been made the subject of much discussion. Of the entire code this section alone has occasioned dissension. The writer of these remarks is one of many who think that the code is here open to objection, not, however, in spirit or intent, but in phraseology. The last sentence is the part concerning which an objection may fairly be raised. At the time when the code was adopted by the American Medical Association, the irregular practitioners, so-called, were, for the most part, uneducated men, whose practice was not only based on an exclusive dogma, but, professedly, to the "rejection of the accumulated experience of the profession, and of the aids actually furnished by anatomy, physiology, pathology, and organic chemistry." They were "steam doctors, or Thomsonians," "botanical or herb doctors," "eclectics," and the like. A system of practice based on the dogmas of Hahnemann had not then acquired a hold on popular favor. A considerable number of those who became homœopathic practitioners, as they are termed, were from the ranks of the medical profession, and had received a regular medical education. Since the adoption of the code, this system has obtained a legal recognition. It has its societies, colleges, and journals. The homœopathic practitioners are an organized class, distinct from the regular profession. They are candidates for practice on the ground of a radical distinction in their therapeutical system, and it is on this ground that patients elect their services. Meanwhile, other systems in antagonism to the regular profession are comparatively insignificant as regards the number of practitioners and of patients.

It is fair to conclude that the framers of the code had no feeling of illiberality, and no intention to interfere with the practice of medicine, under any circumstances, in the cause of humanity. The code declares explicitly that "in consultations the good of the patient is the sole object in view," and enjoins against declining consultations on the score of fastidiousness. The restrictions of the code are in no wise inconsistent with the demands of humanity in cases of emergency. In saying that certain practitioners are not to be considered as regular or fit associates in consultation, it is neither said nor implied that a physician should not see a patient even with these practitioners when humanity requires him to do so. The tenor and spirit of the code throughout are opposed to any act of professional inhumanity. Moreover, in particular cases, the physician must be the judge of his duty in this regard. Practically, there need be no difficulty in deciding how to obey the dictates of humanity, and, at the same time, conform to the code, under the guidance of a conscientious regard for both. The objectionable point in the code is that which makes "a practice based on an exclusive dogma" the ground of a refusal to meet practitioners in consultation. This is not a valid objection. Any physician has a right either to originate or adopt an exclusive dogma, however irrational or absurd it may be. Dogmas have prevailed more or less in the past history of medicine. If in a consultation there be lack of agreement respecting either diagnosis or treatment, the code indicates in another article precisely the course

to be pursued. The true ground for refusing fellowship in consultations, as in other respects, is a name and an organization distinct from and opposed to the medical profession. Whenever practitioners assume a distinctive appellation, thereby assuming to represent an essentially distinct system of practice, taking an attitude of antagonism to the regular profession, seeking popular favor on the ground that they belong to a "new school" based on truth and productive of good, whereas the regular profession belong to an "old school" based on error and productive of harm—how can there be fellowship either in consultations or in other respects? If they who thus assume an attitude of antagonism to the medical profession conscientiously hold to the distinctive tenets which, as they profess, are the ground of their antagonism, how can they consistently desire to meet members of the latter in consultation, and, with opposing views of therapeutics, how could such consultations accomplish "the sole object in view," namely, "the good of the patient"? If, as is asserted, homœopathy has practically been abandoned by most of those who practice under this name, or so modified that the modes of treatment in cases of disease are not essentially different from those of the regular profession, why retain the separate organization and the name, which imply to the public a radical therapeutic distinction? If the assertion be true, the name and the organization being retained, professional fellowship is rendered thereby immoral on the ground of complicity in a fraud upon the public. It is to be hoped that the body from which the code emanated—namely, the American Medical Association—will adopt such modifications in the phraseology of this section as will place restrictions on consultation, not on the ground of doctrines or forms of belief, but on separation from and avowed antagonism to the medical profession. Under no circumstances can there consistently be fellowship with any class of practitioners who adopt a distinctive title as a trade-mark, and who are banded in order to impair the confidence of the public in the medical profession.* To take the ground that, because the Legislature of a State has placed on an equal legal footing different

* The action of the British Medical Association is in accordance with this view. The two following resolutions are quoted from a series adopted by that body:

"Resolved, That homœopathic practitioners, through the press, the platform, and the pulpit, have endeavored to heap contempt upon the practice of medicine and surgery, as followed by members of this association, and by the profession at large.

"Resolved, That for these reasons it is derogatory to the honor of members of this association to hold any kind of professional intercourse with homœopathic practitioners."—*Vide* "British Medical Journal," June 10, 1882.

In these resolutions the repudiation of homœopathic practitioners is based on their attitude toward the practice of medicine as followed by the profession at large, and not on the dogmas which they profess, although in another resolution the latter are characterized as "utterly opposed to science and common sense, as well as completely at variance with the experience of the medical profession." Another resolution is, "That there are three classes of practitioners who ought not to be members of this association [British Medical]: 1. Real homœopathic practitioners; 2. Those who practice homœopathy in combination with other systems of treatment; and 3. Those who under various pretences meet in consultation, or hold professional intercourse with those who practice homœopathy."

classes of practitioners, those of one class can not refuse to consult with those of another class, is as absurd as to assert that a Jewish rabbi is bound to exchange pulpits with Christian ministers, or the latter to affiliate with Mormon elders for the reason that, in the eye of the law, in this country, all religious denominations have equal rights. The people demand of their legislators the enactment of laws for the protection of life, liberty, and property, but they do not look to them for the institution or the interpretation of codes of ethics. If homœopathic practitioners abandon the organization and the name, provided they have received a "regular medical education," there need be no restrictions on consultations other than those belonging to other portions of the code, whatever therapeutical doctrines they may hold.

There are many, not of the medical profession, who have been led to believe that its members are bound to uphold antiquated traditional doctrines. Many seem to think that the "old-school practitioners," as they are derisively called, are committed to a system of practice expressed by the term allopathy. All medical men know that, so far from these popular notions being true, they are quite the reverse of truth. The term allopathy originated with Hahnemann, and was intended to denote a doctrine the opposite to homœopathy. It is simply a term of reproach. It has no pertinency as applied to the medical profession. As is well known by all conversant with the history of medicine, doctrines and practice undergo changes in proportion to the advancement in the several branches of medical knowledge and accumulated experience. The tendency, certainly, within the last half century has been to adopt new views too readily, not heeding sufficiently the restraint of a rational conservatism. It is desirable that the public should understand that the medical profession is in no sense a sect, as implied by the name allopathy. It allows the utmost latitude of opinion. The sectarians in medicine are those who have professed faith in tenets to which they are bound, at least ostensibly, to adhere. Opinions held by members of the regular profession, however at variance with those generally entertained, and however absurd, may fairly give rise to criticism and ridicule, but they can not be made occasions for professional discipline. With a proper understanding of the reasons which actuate members of the medical profession in declining to meet irregular practitioners, their action can not be attributed to either jealousy or prejudice. Their action, indeed, may involve the sacrifice of personal interests, and it concerns the public welfare not less than the dignity and honor of the profession. Let the statement be repeated, until no longer necessary for the information of the public, that there are no allopathic practitioners of medicine. A regular member of the medical profession should never even tacitly admit the propriety of this designation. Let it be understood by the public, as well as by the profession, that there is no necessity for a schismatic separation from the regular profession on account of any peculiarity of doctrine. Such a separation is not from necessity, but for the purpose of obtaining practice. That it is successful for that end, observation shows. Why it is so is a question in psychology, the discussion of which would be out of place here.

SECTION 2. In consultations, no rivalry or jealousy should be indulged; candor, probity, and all due respect should be exercised toward the physician having charge of the case.

SECTION 7. All discussions in consultation should be held as secret and confidential. Neither by words nor manner should any of the parties to a consultation assert or insinuate that any part of the treatment pursued did not receive his assent. The responsibility must be equally divided between the medical attendants—they must equally share the credit of success as well as the blame of failure.

SECTION 10. A physician who is called upon to consult should observe the most honorable and scrupulous regard for the character and standing of the practitioner in attendance; the practice of the latter, if necessary, should be justified as far as it can be consistently with a conscientious regard for truth, and no hint or insinuation should be thrown out which could impair the confidence reposed in him, or affect his reputation. The consulting physician should also carefully refrain from any of those extraordinary attentions or assiduities which are too often practiced by the dishonest for the base purpose of gaining applause, or ingratiating themselves into the favor of families and individuals.

These three sections of Article IV, although not occurring consecutively in the code, are here collocated because they contain ethical rules which have reference to the relations of consulting with attending physicians.

Reference may be made again to the popular errors concerning consultations which prevail to some extent among members of the medical profession. One of these errors is that a consultation, when requested by patients or their friends, implies, as a matter of course, dissatisfaction with the services of the physician in attendance. The request should never be considered in that light. Connected with this error is another, namely, that it is the office of a consulting physician to pronounce a judicial decision respecting the treatment which has been pursued, or which is being pursued, by the physician with whom he is requested to consult. This is not the office of a consulting physician. He should be reserved in forming an opinion as to past treatment, inasmuch as the case was not under his observation, and it would be unfair to judge of circumstances which he had not observed; hence, an opinion unfavorable to the past treatment, if indiscreetly formed and still more indiscreetly uttered to any but the attending physician, might do the latter great injustice. Whatever judgment he may form respecting the treatment which is being pursued, is for the physician in attendance, and for no one else. Still another error is to assume that a physician in consultation has more knowledge or skill than the attending physician, and that, consequently, the latter is to be subordinate to the former in the management of a case. A consulting physician may or may not be the superior in knowledge or skill. Not infrequently a physician is called in consultation for the reason that he has given special attention to the disease from which the patient is suffering; but, exclusive of these instances, a consultation should by no means imply, as a matter of course, a superiority of the consulting physician. These errors, prevailing somewhat in the profession, have a much larger popular prevalence. It is owing to their prevalence that medical consultations are not more frequent. Patients and their friends often hesitate to pro-

pose a consultation from a desire not to imply want of confidence in the attending physician. The physician is often reluctant to propose it lest the proposal be considered as a confession of deficient self-confidence, or because he is distrustful of the one who is likely to be called in consultation, and who is, perhaps, his rival or competitor in practice. Let these errors in the profession and in the public mind be removed, and consultations will be much more frequent than they now are. So far as the physician is concerned, a consultation with those whom he can conscientiously meet on terms of fellowship, and in whose honor he can trust, is a source of much relief and comfort. Aside from any assistance which he may derive from it, the responsibility of the case is divided, and his hands are strengthened by the increased confidence of those most interested. Moreover, rightly conducted consultations tend to enhance popular regard for the medical profession; hence, it is much to be desired that the public should have correct ideas on this subject.

The true ground for a medical consultation is the benefit which may be derived by bringing the judgment of two or more minds to bear upon a case. There are few things in human life which are generally considered more precious than health, and there are few calamities which, in the minds of most persons, it is more desirable to postpone than death. It is, therefore, a singular anomaly that conferences on matters of far less importance than those relating to health and life, such as business interests, politics, social life, etc., are more frequent than medical consultations. In cases of disease, these are frequently delayed until the condition of the patient is hopeless, and when no real benefit can possibly be derived from them. Not only should they be had earlier, but they should not be limited to cases in which there is more or less immediate danger. The fact that they are apt to be thus limited renders them a source of apprehension to patients, and, for this reason, they are sometimes delayed.

The public should understand it to be a point of honor with honorable members of the profession to hold everything which takes place in consultation as secret and confidential. It should be understood that it is improper to ask such questions of the attending physician as "What did the physician in consultation say?" "Did he make any change in the treatment?" etc.; or of the consulting physician, "Does the attending physician understand the case?" "Has he treated it properly?" etc. Sometimes friends of a patient, who are not members of the medical profession, wish to be present at a consultation. This is never allowable. As it may be a matter of delicacy for the attending physician to request them to retire, this should, if omitted by him, always be done by the physician in consultation. A consulting physician is placed in a most constrained situation if, as is sometimes done, the physician in attendance requests friends of the patient to be present. The request should not be acceded to. If the attending physician ask of the consulting physician, in the presence of patients or friends, if there be agreement, the answer should be frank and positive. The consulting physician may sometimes make this statement of his own accord, but it is gratuitous, and may be offensive if made without any intimation of a

want of confidence in the attending physician, or in an assuming, patronizing manner. Unless there be a difference of opinion, which is provided for in another section of this article of the code, an imperative duty of a consulting physician is to sustain and promote confidence in the attending physician. In this way, as well as by any suggestions which he may have made in relation to treatment, he contributes to the "good of the patient."

SECTION 3. In consultations, the attending physician should be the first to propose the necessary questions to the sick, after which the consulting physician should have the opportunity to make such further inquiries of the patient as may be necessary to satisfy him of the true character of the case. Both physicians should then retire to a private place for deliberation; and the one first in attendance should communicate the directions agreed upon to the patient or his friends, as well as any opinions which it may be thought proper to express. But no statement or discussion of it should take place before the patient or his friends, except in the presence of all the faculty attending, and by their common consent; and no *opinions* or *prognostications* should be delivered which are not the result of previous deliberation and concurrence.

SECTION 4. In consultations, the physician in attendance should deliver his opinion first; and, when there are several consulting, they should deliver their opinions in the order in which they have been called in. No decision, however, should restrain the attending physician from making such variation in the mode of treatment as any subsequent unexpected change in the character of the case may demand. But such variation and the reasons for it ought to be carefully detailed at the next meeting in consultation. The same privilege belongs also to the consulting physician if he is sent for in an emergency, when the regular attendant is out of the way, and similar explanations must be made by him at the next consultation.

SECTION 5. The utmost punctuality should be observed in the visits of physicians when they are to hold consultation together, and this is generally practicable, for society has been considerate enough to allow the plea of a professional engagement to take precedence of all others, and to be an ample reason for the relinquishment of any present occupation. But, as professional engagements may sometimes interfere, and delay one of the parties, the physician who first arrives should wait for his associate a reasonable period, after which the consultation should be considered as postponed to a new appointment. If it be the attending physician who is present, he will, of course, see the patient and prescribe; but, if it be the consulting one, he should retire, except in case of emergency, or when he has been called from a considerable distance, in which latter case he may examine the patient, and give his opinion in *writing*, and *under seal*, to be delivered to his associate.

The above rules relate to etiquette in consultations, as distinct from ethics. Of less importance than the latter, they are, nevertheless, important. As it is an essential part of the office of a physician in consultation to co-operate in all regards with the physician in attendance, and to promote the confidence of the patient, he should take pains to treat the latter with becoming consideration and respect. The physician in consultation is supposed to be present at the instance of the physician in attendance; he should certainly decline to be present if not with the full consent of the latter. He is, in the first place, to listen to a recital of the history of the case by the attending physician. This

may be given in the presence of the patient, or not, as the attending physician may deem advisable. Going into the sick-chamber, the attending physician should take precedence, and, if there be more than one physician in consultation, they should follow in the order in which they have been invited to consult in the case. Following this rule without any formal demonstrations will spare occasions for observers to remark how elaborately polite doctors are to each other in consultations. The attending physician should always be the first to approach the bedside and examine the patient, no matter how intimate may be the friendly relations of the latter to the physician in consultation. It is a gross breach of propriety for a physician in consultation to go to the bedside at once and proceed to an examination, as if there were no attending physician in the case. He is to await a request of the attending physician to examine the patient. His examination should, of course, be sufficiently extended, but not beyond the data requisite for forming his opinion. Asking superfluous or irrelevant questions and carrying the examination into needless details belong in the category of "those extraordinary attentions or assiduities which are too often practiced by the dishonest for the base purpose of gaining applause, or ingratiating themselves into the favor of families and individuals." On the other hand, a very cursory examination may give the impression that the consulting physician is able to see at a glance what the attending physician has failed to comprehend, perhaps after much painstaking investigation. Whatever may be the social relations of the consulting physician to the patient, it is but decorous that in the sick-room he should be reserved in both manner and conversation. It is a breach of propriety to be particularly demonstrative or loquacious. To the attending physician belongs the most prominent rôle in the sick-room, without regard to differences in age, experience, or position. Answers to questions by the patient or surrounding friends, addressed to the consulting physician, prior to the consultation, as to the nature of the malady, the gravity of the case, etc., are to be courteously waived.

The attending physician in the consultation-room should have the opportunity of first stating his views concerning the case, if he have not done so already in the recital of the history. He may, however, desire to waive this privilege, and request the views of the consulting physician before stating his own. If he have full confidence in the honor of the physician whom he meets in consultation, he will be unreserved, stating frankly his difficulties and doubts, if he have had any, in the diagnosis and management of the case. The consulting physician, if he find occasion to differ in opinion, should always give due consideration to the fact that the attending physician has had a better opportunity for the study of the case than he can have at a single visit. Allowance is also to be made for changes which are liable to take place in the course of a disease. It is needless to say that any difference of opinion should be stated with respectful courtesy. It is his duty to state any difference of opinion, and he need not feel undue delicacy in so doing, knowing, as he should know, that the difference, if it be not irreconcilable as regards the bearing on the treatment, will never be mentioned by himself outside of the consultation-

room. There is a good reason, when two or more consulting physicians are present, for the attending physician to call first for the views of the youngest, and afterward in the order of juniority. The reason is that the younger will be likely to express his views with more freedom before than after the views of his seniors have been expressed. Moreover, if there be difference of views, it is more decorous for the dissent to come from the older than from the younger of those in consultation. In the great majority of the instances in which there are differences in opinion they relate to points in pathology or etiology, and not to the diagnosis or treatment. There may be wide divergencies of opinion concerning the interpretation of the facts in a case, with complete agreement in respect of the practical points. As regards the latter, in most of the instances in which different views are expressed, they relate to the means of accomplishing certain objects, there being unanimity as regards these. Consultations should not be unduly protracted; if so, patients or their friends are apt to imagine that there is either lack of agreement or some unusual obscurity in the case.

It is the office of the attending physician to communicate to patients or their friends the result of a consultation as regards the nature of the case, the prognosis, and the treatment. He may, however, prefer that this be done by a physician in consultation. If done by the attending physician, it is generally best for the consulting physician or physicians to be present; otherwise, suspicious minds may conjecture that the views of the latter have not been fully or correctly stated. It should be considered a matter of courtesy for the attending physician to ask the consulting physician or physicians if he have stated accurately the result of the consultation, and to invite questions addressed to the latter. Often patients or their friends are not satisfied without some conversation with physicians in consultation. The conversations, however, should always take place in the presence of the attending physician, except the latter desires it to be otherwise. If there exist that *entente cordiale* between the consulting and the attending physician which is desirable in consultations, the latter may request the former to converse with a patient or his friends by himself. Assurances and encouragement may in this way sometimes be more effectual than when given more formally by either when both are present. It should be considered as an insult, except that no improper reflection is intended, when the friends of a patient, after a consultation, seek a private interview with a consulting physician, in order to ascertain whether he really entertained the views which he had expressed or to which he had ostensibly assented. A certain measure of resentment, as well as reserve, under such circumstances, tends to impress upon the public the ethical rule of secrecy as regards the details of medical consultations.

Unessential changes in the treatment of a case should not directly follow a consultation. Inasmuch as the fact that the changes are not essential is not likely to be appreciated, they are apt to be misinterpreted, to the prejudice of the attending physician. Whenever there is agreement as to the treatment which is being pursued, it should, of

course, be continued. It should by no means be considered that, as a matter of course, other or additional therapeutical measures are to be suggested by a physician in consultation. A consulting physician sometimes has unmerited credit in consequence of some trivial modification of the treatment, which is attributed to him. Simple justice to the attending physician dictates great delicacy and circumspection in the suggestion of measures of treatment which are not of immediate importance. It is needless to add that suggestions made for the purpose of giving the impression of a change in treatment are in the highest degree dishonorable.

It may seem a small matter to enjoin punctuality in a code of ethics, but, in reality, the matter is of much importance. Failure to keep an appointment, or tardiness, in the first place, is apt to occasion annoyance to a patient, who may be awaiting the consultation with great anxiety. In the second place, the detention of the one who is punctual may upset all his arrangements for the remainder of the day. There are few engagements with reference to which a prompt fulfillment is of greater importance than medical consultations and other professional visits on the sick. It must, however, sometimes happen that the emergencies of medical practice prevent the fulfillment of engagements. Whenever practicable, the parties interested should be seasonably notified of the inability to fulfill them. On the other hand, it is a breach of etiquette for a consulting physician to arrive at the house of a patient much before the time appointed for a consultation. This is not always easily avoided. If it so happen, he should invariably await the arrival of the attending physician without entering the sick-room; and he should decline to receive a history of the case until he can hear it from the lips of the physician in attendance. In observing these rules of etiquette, he avoids the suspicion of unprofessional conduct by taking a dishonorable advantage of the absence of the physician in charge. Here, as in other instances, the rules by which members of the medical profession are governed should be clearly stated, in order to endeavor to popularize them, and do away with the remark, so often made by those who are not members of the profession, to the effect that they are not acquainted with the requirements of medical etiquette.

How long shall a consulting physician wait for the arrival of an attending physician? The answer to this question will differ in different places. It is desirable that in each place there be some conventional rule in relation to the matter. In the city of New York, about fifteen minutes is considered to be a proper period. At the end of this period, the physician is to decide whether it is advisable to leave and arrange for another appointment, or to see the patient, and leave his views in a sealed note addressed to the attending physician. His decision must depend on the urgency of the case and other circumstances. In everything relating to rules of ethics and etiquette, the dictates of humanity are to be considered as paramount. Whenever the condition of a patient is such as to require immediate measures for relief, a consulting physician, in the absence of the attending physician, is to proceed as if the case were in his charge, giving an account of what he has done, either in a sealed note or subsequently by word of

mouth, to the attending physician. It is superfluous to say that, under these circumstances, the character and the interests of the attending physician are to be carefully and tenderly considered.

SOME OF THE EFFECTS OF NASAL POLYPI IN CHILDREN.*

By A. JACOBI, M.D.,

CLINICAL PROFESSOR OF THE DISEASES OF CHILDREN IN THE COLLEGE OF PHYSICIANS AND SURGEONS, NEW YORK.

THE first case was that of a boy, now about seven years of age, whose history I have known, in part at least, for several years past. I first saw the boy when he was two years and a half old, and was told that he had had a number of attacks of catarrh and bronchitis, and that he had suffered from very severe attacks of dyspnoea, generally coming on at night—attacks which behaved exactly as asthma does in the adult. During the next six or eight months I saw the child a number of times, sometimes when suffering from a well-marked attack of asthma. There were symptoms of an old peribronchitis and emphysema, the latter not very extensive, mostly on the left side and anteriorly. There was very moderate dulness over the larger portion of the right lung, with generally diminished respiration, and also with what was believed to be dilatation of the large bronchus. The child was treated for some time as one would treat an adult for asthma. Considerable improvement followed the administration of the iodide of potassium, and during severe attacks morphine and croton chloral were employed. As a rule, the attacks were easily cut short, but would recur. Great improvement followed a visit to the country, and at the same time the iodide of iron and a little arsenic were administered. The family then moved to Europe, and for some time reported favorably concerning the child's condition; but afterward the attacks returned, and I have heard lately that an operation was performed upon the child's nose six months ago.

The other case, which I first saw about four months ago, was that of a child about three years old, with a similar history. The child had been well up to the end of the first year, when a severe attack of bronchitis set in, and probably interstitial pneumonia or peribronchitis existed. On examination, I found diminished respiration over the whole of both lungs, more marked anteriorly. There was a little emphysema, and the child suffered from quite severe attacks of asthma, usually coming on at night, lasting sometimes a few hours only, and at other times several days. Treatment had already been begun, the iodide of potassium having been given, and also, from time to time, expectorants were administered, and the child had been taken out a good deal. Under this treatment there was said to have been marked improvement. I thought there was hyperemia about the pharynx, particularly on the left side and during an attack of asthma. The child was said to have suffered a good deal from nasal catarrh. The nostril was examined, and a polypus was found and removed. Another made its

* Being the substance of remarks made before the New York Obstetrical Society, February 20, 1883.

appearance, which was also removed about two months and a half ago. Only two paroxysms have occurred since the removal of the polypi, and these were of a mild type.

It seems to me that in the first case, also, the affection must have been due to the presence of a tumor, probably a nasal polypus, which had not been recognized until the child went to Europe, where an operation was performed for its removal. The second case offered no difficulty with regard to diagnosis of the case and its complication, as I had lately read of cases of asthma in the adult accompanied by or dependent upon the presence of nasal polypi. In a number of such cases removal of the polypi has been followed by complete or partial relief of the asthmatic attacks, and the question arises, What is the explanation of the relationship existing between the presence of the nasal polypi and the asthmatic attacks, if any such exists? It is known that the presence of any irritation of a mucous membrane will produce effects not only in the immediate neighborhood of the seat of the irritating body, but also at a distance. For example, a small polypus on the mucous membrane of the rectum in a child is capable, not only by its weight, but by its mere presence, of setting up an irritation both of the mucous membrane itself and of the submucous tissue. Not a small number of cases of prolapsus of the rectum are due to the presence of a polypus situated either upon the sphincter ani or higher up in the rectum, an œdematous effusion taking place, with thickening and relaxation of tissue, leading to prolapsus. It is a matter of every-day occurrence to meet with cases of chronic nasal catarrh or chronic pharyngeal catarrh wherever there is enlargement of the tonsils, whether congenital or acquired, and no method of treatment will prove effectual until the enlargement of the tonsils is relieved. Treatment directed to the condition of the tonsils alone often results in a cure of the nasal catarrh. When, therefore, we speak of a local irritation in such cases, we should not lose sight of the fact that we have to deal, not with a simple condition, but with a complicated one; that what we see is the result of reflex action, for in no other way can the dilatation of the blood-vessels and the over-secretion be explained. The subject of the relationship between asthma in the adult and the presence of nasal polypi was treated of monographically, about six months ago, by Dr. Bregen in Volkmann's "Sammlung klinischer Vorträge."

[When Dr. Jacobi had related these cases at the meeting of the Obstetrical Society, and made the foregoing remarks, the President, Dr. C. C. Lee, spoke of having observed convulsive attacks in children, the cause of which was not apparent unless it was the presence of nasal polypi. Dr. Jacobi then continued as follows:] I have no doubt that the cases related by Dr. Lee were similar, physiologically speaking, to those which I have recited.

There is a fact with which we are all familiar, but which I will mention simply to give prominence to the part played by the nasal mucous membrane in the production of certain nervous symptoms. In chorea minor, which is absolutely local, and gives rise to twitchings of the face, of the eyelids, and of the shoulders, for example, and which is frequently succeeded by general chorea, the affection is due almost ex-

clusively to a local irritation of the mucous membrane, associated with chronic nasal pharyngeal catarrh. In a number of cases I have observed an aggravation of the choreic symptoms attending an acute exacerbation of the catarrh. Now, a relationship exists between the nasal mucous membrane and the nervous system which everybody will recognize, and which probably will offer a satisfactory explanation of at least part of these cases. In the first place, the trigemini with all of its branches is subjected to direct or reflex irritation arising from the inflamed condition of the nasal mucous membrane. Secondly, the thickening of the mucous membrane in the narrow nasal passages of the child, and especially the presence of a polypus, seriously interferes with respiration, and the result is the accumulation of carbonic-acid gas in the brain, particularly about the respiratory center at the medulla oblongata. Thirdly, the lymphatic system of the nasal mucous membrane and that of the dura mater and the arachnoid membranes are in intimate relation with each other, which is so closed that they can be injected from either side. This fact is illustrated in the intimate relationship existing between the lymphatics on the two sides of the diaphragm, where it is frequently found that, as the lymphatics exhibit open stomata above and below, inflammation in the pleura above and of the peritoneum below go hand in hand. Thus it will be seen that there are at least three reasons why there may be an intimate connection between affections of the mucous membrane of the nose and cerebral affections.

LIGATURE OF THE COMMON CAROTID FOR ANEURYSM OF THE EXTERNAL CAROTID; RECOVERY.

By WILLIAM T. BULL, M. D.,

SURGEON TO ST. LUKE'S AND CHAMBERS STREET HOSPITALS, NEW YORK.

The following case is reported as a contribution to the antiseptic ligation of large arteries. A recent collection of cases by Weljamineow ("Centrabl. für Chirurgie," No. 48, 1882) shows these gratifying results: Of forty-seven cases in which the artery was tied for various purposes, but one patient died. Six other fatal cases are included in the collection, but, as death resulted from other causes than the operation, they are not counted.

A muscular, healthy negro, aged twenty-six, was sent into my service at St. Luke's Hospital by Dr. E. L. Partridge, January 2, 1881. Seven months before, he strained his neck in lifting, and a month later noticed a tumor of the size of a hickory-nut on the left side of the neck under the jaw. This had increased steadily in size, and had been constantly painful. January 4th. A firm, rounded, pulsating tumor was found on the left side of the neck of the size of an orange, extending from the lobule of the ear downward in the direction of the sterno-mastoid to the middle of the thyroid cartilage, and forward as far as the anterior edge of the masseter. Pulsation expansile, and stopped by pressure on the common carotid below. A bruit was heard over its lower part only. It was but slightly movable, tender, and the skin over it was normal. There were no enlarged glands; the pupils were normal. The man complained of

constant dull headache, and pain on the left side of the face and neck. January 7th. The common carotid was ligated close above the anterior belly of the omo-hyoid with carbolized catgut under antiseptic precautions (spray). The ligature broke on tightening the first knot, and was replaced by another passing around the artery in the same place. Pulsation ceased; a drainage-tube was placed in the lower angle of the wound; silk sutures and Lister dressing were used.

After the effects of the ether had passed off (six hours later) the left pupil was contracted, the right normal, the tongue deviated to the right side, and there was slight loss of power in the right hand, while the face was drawn to the left side; speech was normal. These symptoms disappeared in a few hours. There was no more pain. Primary union took place. The drainage-tube was removed the eighth day, and the wound was completely closed on the twelfth day without suppuration. (Three Lister dressings.) The aneurysm was smaller and harder, and not tender. He was discharged on the fourteenth day. The tumor continued to shrink, and in three months could not be seen. At present, one year and nine months after the operation, the cicatrix is barely perceptible, and merely an indistinct hardness can be felt at the site of the tumor.

Book Notices.

A System of Human Anatomy, including its Medical and Surgical Relations. By HARRISON ALLEN, M. D., Professor of Physiology in the University of Pennsylvania, etc. Illustrated with three hundred and eighty figures on one hundred and nine plates . . . also upward of two hundred and fifty woodcuts in the text. Section III—Muscles and Fasciæ. Philadelphia: Henry C. Lea's Son & Co., 1883. 4to, pp. iv+243 to 334, inclusive. [Portfolio cover.]

The favorable opinion which we expressed in our notice of Parts I and II of this work is sustained by a careful perusal of Part III. The aim and scope of the work in general have been explained before, so that the reviewer will confine himself exclusively to the section under consideration. It comprises a complete description of each muscle in the body, and, in addition, certain incorporated "remarks" which touch upon the points of clinical interest associated with the more important muscles. In this way a vast amount of research on the part of the author is shown, since case after case is referred to where the muscles of special regions have suffered from the effects of injuries of various kinds. In addition to the clinical matter incorporated, the abnormalities of origin and insertion are discussed, and the surgical relations of muscles and fasciæ are clearly stated when they exist. The use and nerve supply of each muscle are given separately—a plan admirably adapted for reference. In this section of the work, as in those which have previously appeared, the illustrations form an important part. We criticised some of the early drawings as poor, and we are glad to acknowledge that those of this section show improvement, although they are not yet equal to many hitherto published. They are large and distinct as a rule, but coarsely shaded and often out of proportion. A few only are fine and truly artistic. It seems to the reviewer that the incorporation of diagrammatic illustrations of the fasciæ would have added greatly to the value of the

work. It is hard for the general reader to form a proper conception of these structures from descriptive text alone, no matter how carefully worded and complete; while actual representations are difficult to interpret, and are, for that reason, generally omitted.

We are disappointed in the meagerness of cuts to illustrate the perineum. We had hoped to see much originality in the presentation of this important part of the trunk, and to find drawings of the female perineum as contrasted with that of the male. We should have been interested to see the author's conception of the fibers of the levator ani muscle, especially in the female; and drawings, made to show the iliac, obturator, rectovesical, and perineal fasciæ, would have been particularly welcome. As it is, the perineum, with its important muscles and fasciæ, is disposed of in three pages, while the female perineum is not separately considered. It is evident that the section under consideration must have been written before the appearance of some late monographs upon the anatomy of this region; and the author may well consider a complete revision of this chapter in a subsequent edition. It strikes us that the physiological department has again been slighted in the third section. A summary of the action of the separate groups of muscles upon the six principal joints, so tabulated as to make complicated movements understood, would have added to the value of the work. This has been done by several authors of late, and their views could be contrasted with benefit to all who will study a new anatomical treatise with interest. Again, the mechanism of deglutition, respiration, phonation, attitude, etc., properly belongs to the department of myology. As in all first editions, numerous errors of statement have been noticed, but these will creep into text in spite of the most extreme precautions.

Taken as a whole, the third section of this masterly work is entitled to praise of the highest order. It is only because the general excellence of the book is recognized that suggestions are offered which, in the reviewer's opinion, will add to its permanent value and conduce to its success.

Mittheilungen aus der ophthalmiatrischen Klinik in Tübingen.

Herausgegeben von Dr. ALBRECHT NAGEL, ordentlichem Professor der Augenheilkunde und Vorstände der ophthalmiatrischen Klinik an der Universität Tübingen. Erster Band. Tübingen: H. Laupp, 1882. Pp. v+234+118+131. [From B. Westermann & Co. Price, \$4.40.]

This first volume of papers, embodying the work done at the Tübingen Clinic by Professor Nagel and his corps of assistants, is a valuable contribution to ophthalmological science. It is divided into three parts, the first of which contains thirteen papers, some of which are of considerable scientific interest. The first paper is by Nagel, on the Optical Magnifying Power of Lenses and Simple Combinations of Lenses, with reference to the action of spectacles. From a large number of observations and experiments he deduces the following conclusions: 1. Convex glasses magnify, and concave glasses diminish the visual angle. 2. The increase by convex glasses diminishes with the increase of the focal distance, and increases with the refractive power of the lens. 3. The increase by convex glasses increases the greater the distance of the glass from the eye. 4. The increase by convex glasses increases with the distance of the object, as well as with the increase of the distance of the virtual image. The next paper, by Schliephake, gives the results of careful investigation into the effects of muscarine upon the eye. The third paper, by Bisinger, is an interesting discussion of the relations existing between accommodation and convergence of the visual lines. Then follow three short papers upon, 1st, Congenital Coloboma of the Eyelids; 2d, The Ophthalmoscopic

Appearances of Cilio-retinal Blood-vessels; and, 3d, Endothelial Melano-sarcoma of the Ciliary Body. Next comes a lengthy paper, by Schlegel, on the Use of Eserine in Glaucoma, and a short one, by Nagel, on the Ophthalmoscopic Appearances in Myopic Eyes. Two short papers, by Schleich, on the Absorption-Spectra of Cobalt-blue Glasses, and a Rapid Cure of Ananias with white discoloration of the optic nerves; and one by Rembold, on the Condition of the Pupil in Chloroform Narcosis, close this first part of the volume.

The second part contains but one paper, which is a long, interesting, valuable discussion of the movements of the pupil, and their significance in diseases of the central nervous system, by Rembold. It is divided into two sections, the first treating of the anatomy and physiology of the movements of the iris, their causation and conditions; the channels of innervation, oculo-motorius, optic, trigeminus, sympathetic, and peripheral sensory nerves, the posterior columns of the cord and the cerebral cortex. In addition, there are subsections upon the effect of light upon the pupil, the movements of the iris in accommodation, and the state of the pupil in sleep, agony, and death. The second section treats of the condition of the pupil in diseases of the central nervous system, including brain and spinal cord, with subsections upon spastic mydriasis and paralytic myosis. This second part of the volume is well worth perusal.

The third part is concerned almost entirely with myopia. The first paper is by Schleich, and is a Clinical, Statistical Contribution to the Doctrine of Myopia. The second paper is by Weiss, on the Anatomy of the Myopic Eye, and is divided into two parts. The first considers the anatomy of the slightly myopic eye, both macroscopically and microscopically. The second considers the anatomy of the highly myopic eye, with annular staphyloma, both macroscopically and microscopically.

The final paper is a short statistical notice by Nagel of the ophthalmic clinic at Tübingen.

All these papers are of interest, as embodying both a *résumé* of the work done by other writers, and also the results of original observations and experiments by the present authors. This first volume is a valuable contribution to ophthalmological literature, and it is to be hoped that the second volume may maintain the same high standard.

The Chamberlens and the Midwifery Forceps: Memorials of the Family, and an Essay on the Invention of the Instrument. By J. H. AVELING, M. D., F. S. A. London: J. & A. Churchill, 1882. Pp. x-231.

The leading facts brought out in Dr. Aveling's dainty little book are: That in the year 1569 William Chamberlen, a Huguenot, emigrated from France to England, with his family, including a son named Peter; that this Peter Chamberlen invented the midwifery forceps; that another son of William, also called Peter (there being, therefore, two brothers of the same name, distinguished from each other as "the elder" and "the younger"), was the father of a third Peter, who was the first of the family to be admitted to the regular practice of medicine; that Hugh Chamberlen, senior, who was a son of the third Peter, was the one who failed in an attempt to effect delivery with the forceps in a case of dystocia occurring under the observation of Mauriceau in Paris, and was also the visionary busy-body whom Macaulay describes as "pre-eminently conspicuous among the political mountebanks whose busy faces were seen every day in the lobby of the House of Commons," and who finally fled to Holland under suspicion of having defrauded his associates in the Land Bank scheme, and there sold the family secret to Roomhuyzen; that Paul Chamberlen, a brother of

Hugh's, was an unmitigated quack; and that Hugh, junior, the last of the family, led a quiet and respectable life as a physician.

In regard to Dr. Aveling's conclusion that the elder Peter was the real inventor of the forceps, the evidence in its favor is not altogether convincing, consisting mainly in the inference that some of the instruments found secreted in a house that had formerly been owned and occupied by the third Peter antedated the forceps actually used by himself, and in the fact that Smellie, speaking of the instrument employed by the Chamberlens, makes use of the expression "said to be contrived by the uncle," which uncle could have been none other than the first Peter.

Dr. Aveling has corrected some errors that have long passed current in regard to the Chamberlens, and has added materially to our stock of information about the family. His work, therefore, constitutes a notable contribution to the history of obstetrics. It is a very fair reflection, also, of the state of medical ethics in London in the seventeenth century, when the Royal College of Physicians, having been invested with full power to enforce their arrogant pretensions over the surgeons, brooked no infringement of their privileges, but fined every surgeon that had the audacity to prescribe even the most simple internal medication—and that, too, although they themselves were at full liberty to practice surgery.

Living in such times, it is not to be wondered at, says Dr. Aveling, that the Chamberlens failed to feel it incumbent on them to make their invention public. That they were men of great ability can not be denied, notwithstanding their erratic and bombastic character.

BOOKS AND PAMPHLETS RECEIVED

Discursos leídos en la Sesión de Aniversario celebrada por la Sociedad Española de Hidrología Médica el día 4 de Marzo de 1883, por el Secretario General, Dr. D. Benigno Villafraña y Alfaro, y por el socio fundador y de número, Dr. D. José María Bonilla y Carrasco, Presidente de la misma. Madrid, 1883. Pp. 53.

Nephrotomy for Hydronephrosis. Recovery. By A. T. Cabot, A. M., M. D., Surgeon to Out-patients in the Massachusetts General Hospital, etc. Pp. 8.

Safety on Land and Sea. Time without a Watch or Chronometer. Amusement, Instruction, etc. Planisphere of the Stars, improved by Dr. William F. Thoms, President of the American Humane Society, etc. Fifth edition. New York: Published by the author, 1883. Pp. 29.

The 112th Annual Report of the State of the New York Hospital and Bloomingdale Asylum, for the year 1882.

Third Biennial Report of the Trustees, Superintendent, Treasurer, and Architect of the Illinois Eastern Hospital for the Insane, at Kankakee, October 1, 1882.

Fifth Biennial Report of the Trustees, Superintendent, and Treasurer of the Illinois Southern Hospital for the Insane, at Anna, October 1, 1882.

A Manual of Chemical Analysis as Applied to the Examination of Medicinal Chemicals. A Guide for the Determination of their Identity and Quality, and for the Detection of Impurities and Adulterations. For the Use of Pharmacists, Physicians, Druggists, Manufacturing Chemists, and Pharmaceutical and Medical Students. Third edition, thoroughly revised and greatly enlarged. By Frederick Hoffmann, A. M., Ph. D., Public Analyst to the State of New York, etc., and Frederick B. Power, Ph. D., Professor of Analytical Chemistry in the Philadelphia College of Pharmacy. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 624.

The Electric Light in Surgical Diagnosis. By Roswell Park, M. D., etc., of Chicago. Brooklyn, 1883. Pp. 22. [Reprint from the "Annals of Anatomy and Surgery."]

PARTNERSHIPS IN MEDICINE.

THE small prospect of success held out to those who enter upon a medical career with the hope of reaching a high degree of material prosperity is ordinarily narrowed almost to the vanishing point by the consideration that, as a rule, nothing in the shape of pecuniary gain can be counted on, even in the event of a leading position having been attained to, save as the result of personal work—in other words, a lawyer, a tradesman, or even an artisan, provided he is endowed with a modicum of the brain power, and puts into his work a tithe of the energy, that the practitioner of medicine finds essential to the ordinary degree of success, stands a very good chance, not only of earning a competence, but of acquiring wealth, mainly by virtue of his being able to multiply the working capacity of his establishment by adding to the number of those whom he employs, he himself being just as well able to direct the work of a hundred as that of one man; whereas physicians have not usually been able to add to their corps of assistants without lessening their own importance to some extent.

To take the case in which this contrast is least striking, that of the lawyer: when we consult a gentleman of that profession, our contact is likely to be with him only, and whatever admiration we come to feel for the management that must have been brought into play to secure a settlement of the affair in hand to our satisfaction is given to him, although the plan of that management may have been the work of a colleague, and although the routine work was probably done by paid subordinates. Such being the possibilities of the case, lawyers may increase their business to an extent practically unlimited by drawing on the capabilities of their associates, just as a manufacturing house may profit by the special skill of an individual workman in its employ. It is not at all to the discredit of either the lawyer or the manufacturer that he conducts his business in this way; we simply point out that their opportunities are such that they can do so without any disadvantage to themselves or their patrons, and possibly very much in the interest of the latter.

With a medical man, however, the case is quite different. In his work the element of personal service is everything. He must do it all himself, or else bring his patron into direct contact with the man who is actually to do it, knowing full well that the latter and not he himself will get the credit that may come from the service. He, therefore, profits but little in comparison by the services of an assistant, for the assistant has constant opportunities of ingratiating himself with his principal's patrons, and may feel tolerably assured of succeeding sooner

or later to the better part of the practice. Taking this consideration into account, we must say that the terms on which physicians' assistants are usually admitted to a participation in the practice, hard as they may seem to the junior, are not by any means unjust. If young physicians who are not so fortunate as to be able to form such an arrangement think themselves injured by the preponderating advantages it secures to those of their *confrères* who do succeed in the attempt, they may at least console themselves that they suffer for the general good of the profession and for that of the community, for the feasibility of such associations increases the dignity and the emoluments that it is possible for a man to arrive at in a medical career, and thus makes the medical profession more attractive than it otherwise would be to those who are considering the desirability of entering it. Consequently, better men are drawn into the profession year by year—men who are conscious of their ability to win a good position in any one of a number of different callings. Medicine is thus elevated, and the public is better served. Business principles, therefore, have a place among the agencies that are at work in enabling medical practice to keep pace with other pursuits.

But, while we recognize that such is the case, and that, as we remarked before, the principal in a medical partnership risks a good deal, and is fully warranted in exacting services of a high order in return for a very moderate pecuniary compensation, the thing may be carried too far. We should be sorry indeed to see the grinding system in vogue in some countries brought into play here, the feature chiefly objectionable in which is the enforcement of a contract that for a term of years the junior is absolutely bound not to take practice on his own account. This, with some others that might be mentioned, tends to a quasi-slavery that certainly is not conducive to a proper *esprit de corps*. Giving due weight, then, to all we have stated in favor of medical partnerships, we think it would not be well for the profession to have them multiplied at present as they may have to be multiplied when the ranks get to be more crowded, or to have any radical change made in the terms on which they are now generally arranged.

PHYSICIANS' DIVERSIONS.

SOME weeks ago we took occasion to speak of the dearth of channels calculated to lead an unsuccessful or disappointed practitioner of medicine into other pursuits more congenial or more promising. The same lack of opportunity, however, does not hedge the medical man in, if he will content himself with something less radical than an actual change of occupation, and seek what relief there is to be found in mere diversion. Indeed, it is not alone the discontented that need such an occasional shifting of the daily burdens with which a professional man is apt to find himself loaded down. As a people, we are overworked, and it may well be doubted if this is not more decidedly the case with physicians than with most other classes of the community. Not that men in the other professions, and even in mercantile life, are not overborne at times with perplexity and anxiety; but it is assuredly true of most of them

that at least the hum-drum work of their daily life is ordinarily confined within certain specified hours. But the physician, and especially the general practitioner, seldom finds himself quite free from the liability of being called on to do routine work. Even an escape from town brings him little exemption, for the title by which men are accustomed to address him betrays his calling to all those among whom he finds himself, and it is with scant compunction that strangers tax the time and strength of any luckless doctor they may chance to find accessible.

It is not every practitioner who can afford himself even the liberty thus limited. To only a few is the annual trip to Europe open, or even a few weeks' sojourn in the woods or at the seaside. To such as are debarred from these occasional periods of refuge, some diversion near at hand, always available at stray opportunities, might be made of the utmost comfort and usefulness. In the case of city men, a good number find the needed recreation in the clubs; but there are many, and they are apt to be of the finer nature, for whom the club has no very great attraction; and, as a matter of course, our country brethren have no choice in the matter. Still, for one and all, some variation of the constant pot-boiling work is a necessity, and should be so regarded; but, in the great majority of instances, the demands of interest and duty narrow the scope of this possible variation to this, that whatever is resorted to must not involve absence from the post. Practically, then, it is under one's own roof that relief must be sought in most cases.

There are many resources, fortunately, that can be brought within this narrow field. One of these is creeping into favor very widely at the present time. We refer to amateur photography. With an outfit comparatively inexpensive, such as is now to be had in any of our larger towns, and with such instruction as is readily attainable without the aid of a personal teacher, any man at all fitted for experimental work—and none others should be found in our profession—may, with a few weeks' practice, reach such proficiency in the art of photographing as to make its pursuit at odd times a source of no little satisfaction. Even one who may think himself utterly destitute of any artistic turn will be surprised and gratified to find how readily his faculties are drawn in that direction. This, however, is only one of many such resources that might be mentioned; the point is, to lead overburdened men to take up with something of the sort, the particular choice being a matter readily settled by a little thought.

THE UNITED STATES MEDICAL COLLEGE.

We recently chronicled a temporary victory of the Medical Society of the County of New York over that precious institution, the United States Medical College. Already we hear, however, that an attempt is on foot to secure such special legislation as shall legalize the college and protect it against further molestation. In several instances the Legislature of this State has acted with reference to medical matters as if it were bent on preventing the operation of all legal provisions and

natural tendencies calculated to aid in elevating the standard of the profession, and on doing everything in its power to multiply quacks among us. In most of these instances, if not in all of them, it is but fair to say there have been circumstances that gave some color to the idea that the acts in question were passed under a false impression. But in the case of this college we can scarcely conceive that there should be any difficulty in proving to the Legislature that the institution is not simply in the attitude of having neglected certain legal formalities in the matter of its incorporation, but is actually a reproach to the community by reason of the terms on which it grants its diplomas. We are not ready to believe that a majority of the legislators of the State of New York are willing to resort to special legislation for the purpose of propping up an institution the ill-repute of which in other and younger States is so marked as that of the United States Medical College.

We lately received a letter from Dr. James E. Reeves, the Secretary of the State Board of Health of West Virginia, in which, speaking of the college we have referred to, he says: "Three or four weeks ago an itinerant doctor from New York came to Wheeling, to run his speciality of curing piles and expelling tape-worms, armed with a diploma fresh from the establishment above named, which he offered as a basis for registration in West Virginia. On general principles, his diploma was refused recognition." What a praiseworthy piece of work would it be, forsooth, for the law-making power of the great State of New York to gloss over the disabilities of this so-called college, the reputation of which in a sister State is such that the authorities of that State, in the absence of specific information, and acting on "general principles" only, find themselves impelled to refuse recognition of its diplomas!

It should be understood by the Legislature that this college is not persecuted because it is supposed to teach sectarianism, so far as it may by a stretch of the imagination be credited with teaching anything; for the regular medical organization in the State does not now oppose irregular schools of practice before the law. The new code of ethics is really on trial in this matter, for one of the chief of the good results hoped for from it by its supporters was, that it would put the profession in such a liberal attitude before the people of the State that we should soon hear the last of the cry of "persecution" whenever measures were taken to root out an opprobrium. We are quite sure that many of those who lately helped to continue the new code in action did so for the sake of securing this attitude of freedom from intolerance, and the consequent demolition of one of the impediments that have heretofore stood in the way of the influence that the organized profession of medicine ought to be able to bring to bear upon the Legislature. If the Legislature now shows itself not to have been convinced of the disinterestedness of the profession in undertaking such measures for purging itself as are involved in running down the diploma-mill gentry, notwithstanding the position it has taken in its treatment of other schools of practice than its own, either we must settle down to the conviction that our legislators are exceptionally stupid, or else we must confess

that the new code will not bear the interpretation that we supposed would be obvious.

ITINERANT PRACTITIONERS.

By the same letter from which we have quoted in another article, we learn that in West Virginia an itinerant must show himself to be possessed of the qualifications that would entitle him to practice medicine in the State. If he can not show a diploma from a reputable college, he must submit to an examination by the State Board of Health. Having passed that, and been duly registered, he must then pay a special tax of fifty dollars a month, or fraction of a month, in every county he enters. Our correspondent adds that the law is enforced in every instance, and that hence traveling doctors now give West Virginia a wide berth. We esteem it a great favor that the secretary of the board should have taken the trouble to inform us in regard to these matters, and we cordially congratulate our West Virginia brethren on the requirements of the law in their State, as well as upon the fact that their State Board of Health is entirely made up of physicians.

It is not impossible, of course, for a traveling practitioner of medicine to be a creditable member of the profession. Indeed, we once knew of an exceedingly accomplished oculist, an expert operator, a modest and scholarly gentleman, who went from town to town practicing his specialty. He was accustomed to make himself known through the profession only, never resorting to *ad captandum* tricks; indeed, not consenting to receive patients except on the recommendation of their physician. He was a man who might have prospered and been respected had he chosen to fix his abode in any large town, but evidently it suited his restless turn to revive the practice of a bygone age in so far as he was concerned, and his eccentricity can not by any means be taken as affecting the broad proposition that in this period of the world's progress the itinerant practitioner of medicine is almost of necessity an impostor. Certainly the exceptions must be rare.

THE PROPOSED NEW HEALTH DEPARTMENT.

ONE of the features of the bill now before the New York Legislature for changing the charter of this city places the various city departments each under one head, instead of in the hands of a commission as at present; and, of course, it includes the Health Department. Now, our sanitary administration for some years past, in fact ever since the creation of the Metropolitan Board of Health in 1866, has been very creditable on the whole, in spite of some shortcomings. It is to be hoped, therefore, that no hasty action will be taken looking to so radical a change, especially as the appointment of the single officer proposed is to be placed in the hands of the Mayor and the Board of Aldermen. It is not impossible, to be sure, that a man fit for the place may be so appointed; indeed, there might be a good prospect that such would be the case provided the appointing power rested with the Mayor alone, but for the Board of Aldermen to agree to the appointment of a man

whom the profession and the community could look upon as thoroughly qualified to preside over the sanitary administration, is more than experience leads us to hope for.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

A STATED meeting was held January 23, 1883, T. M. MARKOE, M. D., President, in the chair.

COMPLICATIONS ARISING FROM UNDESCENDED TESTICLES.—DR. J. L. LITTLE read the following paper:

There are three positions in which a testicle may be detained in its transit from the abdominal cavity to the scrotum: 1. In the abdominal cavity near the internal ring. 2. In the groin near the external ring. 3. In the inguinal canal.

A number of such cases have come under my observation. The most common variety has been where the testicle was retained just outside the canal near the external ring. I have met with one case, in a child, in which both testicles were retained in the abdominal cavity, as no trace of them could be felt in the canal. A number of cases have been reported in which the testicle in this situation has become the seat of malignant disease; no instance of this kind, however, has come under my observation.

Cases where the testicle is arrested just outside the external ring are not infrequent. In several that I have seen the testicle could be pushed back into the inguinal canal, but as soon as pressure was removed it would assume its original situation. A few years ago I was called to see a patient in whom a testicle in this position was the seat of gonorrhœal epididymitis. It was in a patient of about eighteen years of age who had been suffering from gonorrhœa for some weeks. His symptoms were very severe: constant vomiting, with intense pain in the groin and lumbar regions. Upon examination, a hard swelling was found situated just outside of the right external ring, with the absence of the testicle from the scrotum. This swelling was of about double the size of the testicle of the opposite side, and resembled a strangulated hernia both in symptoms and in appearance. The history and the absence of the testicle from its normal situation were sufficient for diagnosis.

Second. On August 17, 1868, I was called to see a patient who had a strangulated hernia. His history was as follows: He had suffered from what he supposed was a femoral hernia for many years, for which difficulty he had been in the habit of wearing a truss. The morning on which I was called he had gone out for an early drink, and neglected to apply his truss. The rupture came down and became strangulated. Upon examination, I found a tumor of about the size of an orange on the right side, just above Poupart's ligament, resembling in many respects a femoral hernia which had rolled up over the ligament. Failing to reduce it by taxis, I etherized the patient, and found upon examination that he had an undescended testicle situated just outside of the external abdominal ring, and that the tumor was formed by the distension of the inguinal canal. Failing to reduce it by taxis under the anæsthetic, I cut down through the walls of the canal, and found about ten inches of the gut in a strangulated condition. The seat of the stricture was at the internal abdominal ring. The testicle was lying internal to and behind the gut, just outside the external ring. The internal ring was enlarged and the gut returned, and the patient made a good recovery. In this case the testicle was normal in size and ap-

pearance, and I have no doubt could be easily pushed up into the canal, so that his truss was worn without inconvenience.

The next case, sent to me by Dr. William A. Hammond, is one in which the testicle was retained in the inguinal canal. The patient was twenty-six years of age, and had the following history: He had never noticed anything like a testicle on the right side until three years before he came under observation, when, while exercising on a trapeze, he received a blow on the right side of the abdomen, which gave rise to severe pain, similar to that produced by pressure upon the testicle of the other side. About a month after, he noticed a small and soft tumor on the right side, just above the external ring. From that time, after any violent exercise, straining, or long walking, the tumor would increase in size, and become very painful. After a few days the swelling would subside, but the tumor would never become as small after an attack as it was before. Last winter the patient wore a truss for some time without any benefit. The tumor gradually increased in size. On examination, only the left side of the scrotum was found to be developed, which contained a testicle of normal size. In the right inguinal region was a swelling extending up in the direction of, but some distance above, the inguinal canal. A moderately firm and perfectly movable tumor could be felt. This could be moved so as to lie almost at right angles to its normal attitude. Firm pressure upon the upper part of the tumor gave rise to a sensation similar to pressure upon a testicle. The tumor was about four inches long by two inches broad. The external abdominal ring could be distinctly felt, but was so small that the little finger, in invaginating the tissues, could not be passed into it.

On November 24th the following operation was performed at St. Luke's Hospital with all the antiseptic precautions. The coverings of the tumor were rendered as tense as possible by grasping it with my left hand, and an incision about five inches in length was made over the most prominent part, nearly parallel to Poupart's ligament. The tissues were divided until the peritoneum was reached. This was opened upon a director, and the tumor was then forced out from its bed. Its attachments were composed of folds of peritoneum extending along

its entire inferior surface; a large number of tortuous vessels were seen beneath this peritoneal pedicle, more abundant at the upper extremity than at the other portions. A double catgut ligature was passed through the center of the pedicle and tied on both sides. Another ligature was applied embracing both halves of the pedicle, and the tumor was then removed. No exploration of the wound with a view to ascertaining whether it communicated with the abdominal cavity was made. The deep parts of the wound were brought together with three Lister's leaden plate sutures, and the superficial wound was united by the ordinary silk suture. The wound united by primary union, without any untoward symptom.

On examination by the pathologist of the hospital, Dr. Satterthwaite, this tumor proved to be a round-cell sarcoma. In shape it was a flattened ovoid, while its dimensions were four inches in length by two broad and one inch and a half thick. On section, its cut surface was of a pinkish color, simulating brain substance both in consistence and in feel. It was inclosed in a coat of peritoneum, which formed its capsule, while in the folds that were given off posteriorly were portions of the vas deferens and spermatic vessels. At its anterior and external portion there was a trace of the normal tissue of the testis.

In conclusion, it seems to me that in all cases where a testicle is situated either in the canal or just outside the external ring, and becomes a source of annoyance to the patient, it would be judicious to advise its early removal.

In the case which I have related complicated with hernia, I have since regretted that I did not remove the testicle at the time of the operation, for, unless it can be readily pushed back into the canal, a condition which would hardly obtain after the operation, a truss would be worn with considerable difficulty. I have never had the means of ascertaining the after-condition in the case related.

Dr. E. L. Keyes had had one case, complicated by omental hernia, in which the undescended testicle could not be kept outside the external ring by a truss, although it could be easily pushed through the opening. The patient had had a number of accidents in the way of pain; and at intervals, when he did not wear a truss, the hernia would get down and cause a swelling in the groin, which he had always been able to replace. Finally one of these swellings occurred during the absence of the truss, and the patient failed to replace the lump. He then suffered from symptoms arising from partial strangulation, continuing for a number of months. Dr. Keyes operated upon him, and found that he had a hard portion of omentum strangulated at the internal ring, with a testicle just below it. He removed the atrophied testicle, and cut off the piece of strangulated omentum. He ligated the cord very high, and left the pedicle of the omentum in the internal ring, which was entirely filled by it. The operation was performed, under antiseptic precautions, about ten years ago, and the patient made a rapid recovery. He subsequently wore a truss for a considerable period, after which he experienced no trouble whatever. He had also since become the father of several children. The other testicle was normal in structure and position.

Whether it was justifiable to cut out the testicle in these cases before some emergency required the operation, he was uncertain; he was not prepared to say that he would advise it. He had frequently seen these undescended testicles in young children, and believed that, if sufficient care and attention were given, the testicle might be gradually pulled down, and finally be made to remain permanently outside the external ring, in a certain proportion of cases, until it developed at puberty, and then no further trouble would follow. But it was exceedingly difficult to get a retentive pad that would act satisfactorily, even if the testicle could be drawn down and held outside the

external ring with the fingers. In answer to a question asked by the president, Dr. Keyes said that he had had one case in which he succeeded in keeping the testicle outside the external ring, but he was not able to replace it in the scrotum. To succeed in any of these cases required a long time, and great care and patient attention on the part of all concerned. He had failed in the effort several times.

Dr. SANDS said that Dr. Little had made one remark which perhaps should be qualified, he having suggested that whenever a testicle situated in the inguinal canal became an annoyance it should be removed. It was well known that the operation for the removal of a testicle situated in the inguinal canal was one of much greater danger than the ordinary operation of castration, which was attended with little risk if carefully performed. But, when the testicle was situated in the inguinal canal, it was very liable to be surrounded by peritonæum, which might have to be divided in order to remove the tumor, and it seemed to him that such an operation should hardly be performed for the relief of a mere annoyance. He did not doubt, however, the propriety of removing a testicle so situated when it became the seat of a morbid growth, although, under these circumstances, the operation was attended not only with greater risk than the ordinary operation of castration, but with a greater improbability of a complete removal of the disease. He thought that in quite a large proportion of the cases in which it had been done the malignant disease had already involved the lymphatic glands in the abdominal cavity. Here it might be said that valuable evidence could sometimes be obtained on this point by manual exploration of the rectum. A man came under his observation in Bellevue Hospital, some years ago, who entered the institution for the purpose of submitting to castration. The left testicle was very much enlarged, and the diagnosis of malignant growth of the testis was readily established. The tumor was so large, however, that it was suspected the disease had extended into the abdomen. Dr. Sands was unable to settle this point by external examination, on account of the thickness of the abdominal walls, but he found, upon making firm pressure in the left lumbar region, a tenderness and a feeling of resistance not noticeable upon the opposite side. He removed the doubt by passing his hand into the rectum, when, with great ease, a swelling could be felt in the abdominal cavity, evidently due to infiltration of the lumbar glands; accordingly, he abstained from operation.

He recalled another case in which he failed to appreciate the presence of an abdominal tumor in a young man whose testicle he had previously removed for sarcoma. The patient made a good recovery, but months afterward he showed signs of suppression of urine, and, on this account, he came under observation a second time. Examination of the abdomen failed to discover the cause of the trouble. Various medicines were given to cause the kidneys to act, but they failed. Death occurred, and inspection of the abdomen revealed a large mass of cancer situated upon the posterior abdominal wall, probably originating in the lymphatic glands. The mass was so situated as to completely prevent the passage of urine through the ureters, and the so-called suppression of urine was really retention of urine, both of the ureters being greatly distended above the points of obstruction.

He had met with one instance in which the testis had descended beyond its usual position, and was situated in the perinæum. The person who was the subject of this malposition was a young man, who complained that he was unable to ride on horseback without suffering from pain due to pressure upon the misplaced organ, which was of about half the size of the opposite testicle. Dr. Sands performed an operation, with the intention of placing the testis in the scrotum; but he found the

operation to be impracticable, and, therefore, removed the testicle, when all unpleasant symptoms disappeared.

Dr. LITTLE stated that Mr. Curling gave the same advice in regard to the treatment of undescended testicle as that suggested by Dr. Keyes, and related several cases in which a truss was used to prevent the testicle from slipping back through the external ring into the canal. Mr. Curling also advised that in cases where the testicle was situated in the inguinal canal, and could readily be pushed back into the abdominal cavity, the patient should wear a truss with a pad over the inguinal canal, so as to keep the testicle back in the abdominal cavity, it being a much more comfortable place for the patient to wear his testicle than in the canal.

Dr. YALE said that the latter point mentioned by Dr. Little was illustrated in a case which came under his observation in the Presbyterian Hospital. A young man had a partially descended testicle. He had been examined, and had been told that he had a hernia, for which a truss was applied, and it had the effect of crowding the testicle back into the abdominal cavity; but subsequently a strain brought the organ down into the inguinal canal, and he had considerable pain, together with symptoms not unlike those attending strangulated hernia. As the testicle could not be brought farther down, Dr. Yale, with considerable difficulty, succeeded in returning it within the cavity, when the symptoms were relieved, and no further inconvenience had been suffered from the presence of the testicle in the abdomen.

Dr. KEYES said that Godard directed attention to the fact that the cryptorchid was sterile, while a monorchid was not sterile; that the testicle was more or less damaged if it was retained in the inguinal canal; that those which were retained just within the inguinal canal were in a condition of partial atrophy, and that the other testicle was correspondingly hypertrophied. Whether this partially atrophied testicle was incapable of secreting sperm properly, Dr. Keyes was unable to say; also whether, if the testicle was in good condition, it would be harmed by being pushed into the abdominal cavity and retained there, he was unable to say. He had met with one cryptorchid, and in that instance the man was potent, and had emissions, but he was sterile. His seminal fluid contained no mature spermatozoa.

Dr. POST asked if cryptorchids could beget children.

Dr. KEYES said that such cases were upon record, but that the children did not generally resemble the father; that is, so far as he knew, all such cases of alleged paternity had been shrouded in considerable doubt.

Dr. SANDS thought it would be unsafe to say that testicles were useless in persons who had power of copulation. There was no exception to the rule that where both testicles were removed the power of copulation remained for only a time. Sir Astley Cooper had recorded one case in which a man had lost both testicles, but retained the power of copulation for perhaps a year, after which the desire and the power gradually ceased. He believed that usually the desire and ability to copulate implied the existence of some testicular elements, although the general fact was that those who had both testicles retained were usually sterile. He thought that if subjects who were sterile had normal desires, and were able to gratify them, the most rational supposition would be that normal tissue of the testicle existed in a greater or less amount, but that the spermatic fluid was unable to make its way into the seminal vesicles. He had met with a singular instance of undescended testicle in the case of a young man upon whom he once operated for strangulated hernia. The case was interesting as showing that a concealed testicle might give rise to a peculiar form of hernia. The man was twenty-five years of age, and was said to have been addicted to sexual dissipation. His scrotum was empty, and he

had a hernia upon the left side, which became strangulated. Dr. Sands found, upon proceeding to the operation, that only a very slight protrusion existed at the external abdominal ring, in consequence of its small size. Having divided a stricture at the external abdominal ring, and, as he supposed, pushed the intestine back into the abdomen, he introduced his finger, and discovered that he had not relieved a strangulation which existed at the internal abdominal ring, and that, while only a small portion of the intestine had escaped through the opening in the external ring, a large mass remained in the inguinal canal. The stricture was divided at the internal ring, and he was then able to push the intestine into the abdominal cavity, for which he had at first mistaken the hernial sac. A small testis was found in the inguinal canal. The person had a well-developed penis, and had an abundance of hair upon the pubes. He also had a beard. Dr. Sands thought that in most cases in which the testicles were retained, and the individual impotent, there were but few evidences of puberty.

Dr. G. A. PETERS asked if a testis retained in the cavity of the abdomen was not quite frequently the seat of malignant disease, or more frequently thus affected in that position than when within the canal or just external to it.

Dr. KEYES remarked that there was an impression to that effect, but he did not believe that the statistics had been sufficient to substantiate it.

Dr. LITTLE remarked that cases had been reported in the "Medico-Chirurgical Transactions," "British Medical Journal," "Medical Times and Gazette," and other journals, where undesecured testicles had become the seat of malignant disease. And authors, for instance Gross, in his work on surgery, stated that the danger of the detention of the testicle in the inguinal canal or abdominal cavity was, that it was prone to become the seat of malignant disease; but no statistics had been given to sustain this statement.

DERMOID CYST OF THE OVARY.—Dr. F. LANGE presented a specimen removed from a patient thirty years of age. It contained a large mass of hair and some bone. One portion presented an appearance almost exactly like a piece of the scalp, and it was from this part that the hair took its origin. There had been a variety of opinion with reference to the nature of the tumor, but for the most part it was regarded as a solid growth and in close connection with the uterus. At the time he saw the patient it had become quite clearly established that the tumor contained considerable fluid, that probably the uterus had been entirely crowded to the left side, and that the growth did not have its origin in that organ. It seemed, by internal examination, that the tumor was situated in the broad ligament. The operation was very difficult in consequence of the absence of a pedicle and the presence of extensive adhesions. Many ligatures were applied to the adhesions, which were cut in each instance with the actual canter, and the wounds were powdered with iodoform. Although the operation lasted two hours, the loss of blood was insignificant. The left ovary was also removed on account of cystic degeneration. It was of about the size of a small hen's egg. Scarcely any reaction followed the operation; at no time did the temperature rise above the normal. He thought that the patient was out of danger. The operation was performed eight days ago. It was the second dermoid cyst which he had removed within the last three months. The former was from a girl nineteen years of age.

[At the time of writing the patient is out of bed and out of danger.]

STRAIGHT URETHRAL SOUNDS.—Dr. POST presented several samples of straight steel sounds for treating strictures in the straight portion of the urethra. The advantage claimed for

them was that they could be used with greater facility than the curved instruments, and that, when given a rotary motion, they caused less pain. One was fusiform in shape. They measured 25 centimetres in length, 27 millimetres in circumference round the bulb, 34 millimetres at a distance of 7 centimetres from the bulb, and 30 millimetres 12 centimetres from the handle.

PHARYNGEAL TUBES.—Dr. L. A. STIMSON said that since the last meeting of the society, at which Dr. McBurney read a paper on tracheotomy as a preliminary operation, he had had a patient under his care with a tumor of the superior maxilla, and it had occurred to him that possibly a substitute could be devised for the tracheotomy tube, consisting of a tube to be introduced through the mouth into the pharynx, the space around it to be blocked with sponges in a manner which would prevent the passage of blood into the pharynx, air-passages, or œsophagus. After talking the matter over with Dr. McBurney, who had conceived the same plan independently, and following Dr. McBurney's suggestions with reference to details, an apparatus was constructed which consisted of a tube six or seven inches in length and of the diameter of a No. 38 urethral sound, about an inch and a half of its extremity curved to almost a quarter of a circle, and provided with a flange one eighth of an inch in breadth, perforated with small openings, through which threads could be passed. About that curved portion he tied a sponge, stitching it fast to the flange and placing behind it a piece of impervious tissue, in order to favor the retention of such blood as might soak through the sponge. After complete anæsthesia had been produced in the usual manner, the tube was passed into the mouth and carried well down behind the root of the tongue, but it caused so much gagging that it was necessary to withdraw it until it reached only a little behind the uvula, so that the patient still breathed partly through the nose. While the preliminary incision was being made and the flaps were being dissected up, sponges were placed between the teeth, and this packing proved very satisfactory indeed. The patient was able to breathe. Anæsthesia was maintained without difficulty through this tube, and, although he bled very freely, the sponges caught all the blood, and it was only necessary to change them as soon as filled. After the flap had been dissected and bleeding points secured, the hæmorrhage was inconsiderable. During the piecemeal removal of the growth, which included all the right and a portion of the left superior maxilla, and left a cavity which opened into both nostrils, and backward into the pharynx above the soft palate, there was no trouble whatever from the bleeding. Sponges were kept behind the surface of section and caught all the blood. The tumor was an ordinary carcinoma, and the only point concerning it which was remarkable was the fact that it had so affected the gum corresponding to it that a small fragment snipped off for microscopical examination presented all the appearance of epithelioma, even to the completely formed nests of cells. This appearance of epithelioma was due to secondary change of the papillary layer of the gum. The true tumor itself was an alveolar cancer, which had evidently originated farther back and in the substance of the bone.

Dr. Stimson said that he was aware that tubes had been devised to pass into the trachea, but that was not the intention in his apparatus. It was his intention that it should not pass beyond the pharynx. The suggestion was so simple that he thought it must have been acted upon by others, and he had shown the instrument to the society in the hope that further trials might be made with it which would increase its efficiency.

NECROSIS OF A COSTAL CARTILAGE.—Dr. J. C. HEDDERSON presented a portion of the cartilage of the eighth rib removed from a man fifty years of age, who two years previously had

typhoid fever which lasted for a considerable time. Six months later he had two abscesses over the cartilage of the rib—one at the junction of the cartilage with the rib, and the other where the cartilage joined the sternum. A probe reached the cartilage very readily, and during the last two months he had been able to push the probe apparently into the cartilage. Latterly the patient had suffered considerable pain, especially upon coughing, and Dr. Hutchison determined to remove the diseased portion, which he did by making an incision directly over the cartilage. The perichondrium was separated from the cartilage, and a chain-saw carried about it very readily, near the point where it joined the rib, and he subsequently discovered that there was separation at that point. The cartilage at the point where it joined the sternum was easily snapped off. On examination, he found that the disease was confined to the anterior portion of the cartilage. He, however, removed the portion which remained, so that the entire cartilage was removed. The end of the rib was perfectly healthy. The case was the only one which had fallen under his observation of disease of cartilage of the rib.

NEURALGIA OF THE INFERIOR DENTAL NERVE FOLLOWING FRACTURE OF THE LOWER JAW.—Dr. STIMSON narrated a case in which the patient, after the lapse of seven months, suffered from neuralgia following fracture of the lower jaw. The fracture was on the left side and united with some displacement. The patient returned to him in December, complaining of numbness and sensitiveness in the region of the cutaneous distribution of the inferior dental nerve, and also of inability to properly masticate because of displacement of the jaw. Dr. Stimson found that the difficulty in mastication was due to depression of the anterior fragment, and he relieved it by gouging away a portion of the posterior fragment which interfered with an upper molar. The union between the fragments was fibrous, and a temporary increase of the slight mobility followed the operation. The pain increased afterward to such an extent, although it was temporarily relieved by the use of an interdigital splint, that the patient returned and demanded some operation for her relief. Pain upon pressure over the mental foramen was acute, and also along the course of the inferior dental nerve before its entrance into the canal. He exposed the nerve before its entrance into the canal by the usual incision within the mouth, raised it up, and divided it. He desired to excise a portion, but was unable to hold it with the forceps so as to remove it. Relief was immediate and complete for perhaps ten days, but sensitiveness then again began to return in the region of the nerve just where she formerly complained of it when the mental foramen was pressed upon.

Dr. HALSTED referred to a case in which he excised about one centimetre from the inferior dental nerve. The neuralgia was severe, but relief was given. He found excision of a portion of the nerve very difficult to perform.

Dr. STIMSON referred to a case in which Dr. Sabine had divided the inferior dental nerve for the relief of neuralgia, and in which Dr. McBurney subsequently removed a portion of the nerve. The excision was followed by a cure which had now lasted for one year.

Dr. HUTCHISON referred to two instances in which he succeeded in curing obstinate neuralgia by ligation of the carotid artery.

Dr. LANGE referred to a case, already reported to the society, in which the patient had had a variety of operations performed with a varying amount of relief, but permanent relief had not yet been obtained.

Dr. STIMSON remarked that the traumatic origin of the neuralgia in his case seemed to him to be sufficient to justify the division of the nerve above the point of irritation.

QUARTERLY REPORT ON OPHTHALMOLOGY AND OTOTOLOGY.

No. XIII.

By CHARLES STEDMAN BULL, M. D.,

LECTURER ON OPHTHALMOLOGY AND OTOTOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO THE NURSEY AND CHILD'S HOSPITAL.

(Concluded from page 361.)

IMPROVEMENTS IN THE EXTRACTION OF CATARACT.—Wecker (*ibid.*) reports a number of improvements which he has made in operating for cataract, which concern three points: 1. The closure of the wound. 2. Direct disinfection. 3. The disengagement of everything which might become fastened in the wound. During the sixteen months since June 6, 1881, he has performed three hundred and sixty-six extractions without a single case of suppuration; and these exceptionally good results, he thinks, are due to a careful carrying out of the improvements in relation to the three points just mentioned. After the cataract has been extracted, he carefully removes with a rubber spatula all bits of lens matter, blood clots, etc., from beneath the central and lateral conjunctival flaps. He then adjusts these in apposition with the neighboring conjunctiva, and presses them against the underlying sclera. Direct disinfection of the wound is the second modification. He carefully cleanses the conjunctiva and the ciliary border of the lids with a four-per-cent. solution of boric acid and a one-per-cent. solution of salicylic acid. Whenever he uses a spatula, it is first dipped in a two-and-a-half-per-cent. solution of carbolic acid, and he also bathes the wound with the same solution. The third point is to avoid, as far as possible, all adhesions of iris and capsule in the wounds. In making his incision, he penetrates vertically into the anterior chamber with the point of a knife, planted exactly at the sclero-corneal margin, so as to equalize the extent of the exterior and interior lip of the wound near the points of puncture and counter-puncture. Moreover, he endeavors to make the apex of his incision agree with that of the vertical diameter of the cornea, so that the pressure may be sure to act in the line of the maximum opening of the section. For this purpose he uses during the operation oblique illumination. To facilitate this, he adjusts to the side of the operating chair or table a lamp constructed for the purpose. This lamp slides up and down on a vertical standard, to which it may be firmly fastened at any desired height by means of a screw clamp. This lamp carries a magnifying lens, by means of which the light is focused on the eye.

TRANSPLANTATION OF SKIN-FLAPS WITHOUT PEDICLES IN BLEPHAROPLASTIC OPERATIONS.—Wicherkiewicz ("Kl. Mon. f. Augenheilk." Dec., 1882) takes up the subject of blepharoplasty by means of transplantation of flaps without pedicle, and discusses it in all its bearings. He first cites those cases which have been published by various ophthalmic surgeons, and then gives in fullest detail the histories of three cases of his own, and his general conclusions are that, while Wolfe's operation has considerable value, it does not always give the brilliant results which have been claimed for it. First of all, he thinks that antiseptic measures should not be carried so far as to cauterize or chemically alter raw or freshly wounded surfaces. The application of artificial warmth is of importance in those cases where the coaptation of the skin-flaps is protracted by the introduction of many stitches; but it should be avoided where considerable parenchymatous hæmorrhage is produced by it. He does not

consider that sutures are always disadvantageous, for they often aid very efficiently the coaptation of the flaps with the edges of the surrounding skin. An intimate, lasting union of the transported flap with the underlying raw surface is necessary to complete success. In the future Wicherkiewicz would modify Wolfe's method by applying the transplanted flap without pedicle not upon a fresh, raw surface, but upon one which is already covered with granulations. He recommends the following procedure: If it is a case of ectropium, where there is not sufficient material for transplanting a flap with a pedicle, he detaches the everted lid completely from its cicatricial bands, excising, if need be, all cicatricial bands, and then stitches the edges of the lids together for a short distance. He then closes the wound antiseptically with boracic- or carbolic-acid dressings, or dressings of iodoform ointment. As soon as healthy, fresh-red granulations have covered the defective surface, which usually occurs in from ten to twenty days, he covers this surface with a flap, the exact size of the granulating surface, removed from some appropriate spot, having first washed the surface with one half per cent. carbolic-acid solution, and cleared it of all coagula. He then covers the flap and surrounding region with a piece of linen which has been coated with an eight per cent. boracic-acid ointment, or a three per cent. carbated vaseline, and over this a somewhat larger piece of rubber paper or cloth; then a thick layer of borated cotton, and over all numerous turns of a gauze bandage which has been soaked in a five per cent. carbolic-acid solution. This dressing is not to be removed for four days, and, when it is removed, it should be done under the spray, and re-applied in the same way.

OTOLOGY.

THE VASO-DILATOR NERVES OF THE EXTERNAL EAR.—DASTIC and MORAT ("Arch. de Phys.," Oct. 1, 1882) have been making some quite extensive investigations into the vaso-motor nerves, especially with reference to the external ear, based upon experiments upon dogs and rabbits. They are of the opinion that the local variations in the caliber of the vessels are dependent upon the contractile power of the vessels themselves, for, examined simultaneously in different regions, they present no agreement with each other. They, therefore, can not depend directly upon a temporary, rhythmic augmentation of the force

of the heart's contraction. They are simultaneous in symmetrical regions, as observed in rabbits' ears. The vascular muscle is thus to be regarded as antagonistic to the cardiac muscle. It is admitted by most physiologists that the dilator nerves of the vessels may be found in all nerves except the sympathetic. As a matter of fact, constrictors and dilators arise very near each other. They make their exit either by the same roots or by roots very near each other, and run usually in the same trunks. Irritation of one set is scarcely possible without irritation of the other set, and the effect observed is the resultant of two antagonistic actions. The vaso-dilator nerves of the external ear arise from the spinal cord in the upper part of the thoracic region, which is very near the origin of the vaso-constrictor nerves. These vaso-motor nerves together, therefore, form a very circumscribed, centralized system. The authors' experiments have demonstrated the absolute difference in result between irritation of the thoracic sympathetic and irritation of the cervical sympathetic. Irritation of the cervical sympathetic contracts the vessels of the ear, while irritation of the thoracic part in its upper part dilates them. The point where the effects of irritation are reversed is marked by the presence of a large ganglion, the first thoracic or inferior cervical ganglion. The most simple explanation of this phenomenon is that the dilator fibers terminate in the ganglion itself; and their action can only be understood by supposing that they end in ganglionic cells situated in the course of constrictor fibers, the tonic action of which they are thus able to suspend. In the reflex dilatation of the vessels of the ear, the nerve which determines the dilatation is the auriculo-cervical, a branch of the cervical plexus and the principal sensitive nerve of the tympanum. This nerve contains elements coming from the second cervical, and a small number of elements coming from the third cervical. The study of reflex dilatation of the vessels of the external ear fully confirms the results obtained in investigating directly the vaso-dilator nerves of this organ. All these experiments led the authors to the same conclusion, as follows: A notable proportion of the vaso-dilator nerves of the ear is contained in the sympathetic nerve trunk, and arises in that region of the spinal cord called by Budge and Waller the cilio-spinal center. From this same region arise the dilator nerves of the iris, and the secretory and constrictor nerves of the vessels of the face. From further experiments, it seems possible that these vaso-dilator fibers of the ear may have two origins—one in the spinal cord, and another, more problematical, in the medulla. After division of the cervical or thoracic sympathetic, reflex irritation of the centers provokes a still greater degree of vaso-dilatation, which must be attributed to the action of the nerves of the medulla, since by reason of the division of the sympathetic the spinal cord has no connection with the dilated vessels.

AN ATTEMPT TO FORM AN EXTERNAL AUDITORY CANAL IN A CASE OF CONGENITAL MALFORMATION.—Kieselbach ("Arch. f. Ohrenheilk.," xix, 2 and 3) reports a case of this nature in a female child aged six months, the child being in other respects well formed. Both auricles presented the appearance of being pressed forward and bent over by a force working from behind, the malformation being most marked on the left side. No verbal description of the deformity will give a clear idea of the case. In operating for the discovery or formation of an external auditory canal, Kieselbach made an incision through the little groove behind the rudimentary tragus into the subcutaneous adipose tissue. Pushing this incision down to the periosteum, not a trace was found of any auditory canal. He then cut carefully downward as far as the lower squamous border. Here the introduction of a fine probe discovered a narrow cleft, which was widened forward and backward until the probe in all directions encountered firm resistance. In order to prevent

the readhesion of these wall-surfaces, the lobe was detached from the auricle and its length doubled by an incision which split its surface from the anterior half of its insertion nearly to its posterior border. This flap was then thrust into the wound, so that its skin-surface was turned toward the annulus tympanicus, and its raw surface toward the lower and outer surface of the wound. The flap was then fastened in place by means of quilted sutures. It was later the intention to introduce a small tube in order to keep the skin-flap better in place, but the child was removed from observation before this could be done.

BILATERAL DEAFNESS FROM MUMPS.—Knapp ("Arch. of Otol.," xi, 4) reports a case of this kind in a young woman, aged twenty-five. Six years previously she had had an acute attack of mumps on both sides, which lasted two weeks. Hearing became affected on the seventh day, was completely lost on the eighth, and has remained so ever since. There was pain in the ear and head, but no discharge. She suffered from great dizziness, which lasted for months, and, in fact, has never completely disappeared. There has never been any tinnitus. Careful examination showed absolute deafness on both sides. Physical examination of the ears, Eustachian tubes, and naso-pharynx revealed perfectly normal conditions. All the symptoms, Knapp thinks, pointed to a labyrinthine lesion, but whether of a serous, hemorrhagic, or purulent inflammation, can not be decided. A direct continuation of the disease through the auditory canal and tympanum, or through the canal of the facial nerve, is vague and improbable. He regards the trouble as metastatic in nature.

THE APPLICATION OF A DISINFECTING APPARATUS TO THE AIR-DOUCHE.—Lucas ("Arch. f. Ohrenheilk.," xix, 2 and 3) calls attention to the necessity of keeping pure and clean the air which is to be blown into the middle ear, and thinks with Zaufal that the simplest way to do this is by inserting between the air-bag and its nozzle of exit a capsule filled with salicylated cotton. He believes that the nearer the disinfecting apparatus is brought to the ear the more sure is the purification of the air likely to be, and recently he has arranged its introduction into the catheter itself. He has had a silver catheter made with an arrangement like a Böttcher's inhaler near the outer end, which can be unscrewed and its cavity filled with salicylated cotton before introducing the catheter into the nostril. He keeps his catheters and the olive-shaped ends of his inflating apparatus in a solution of carbolic acid, in order to avoid, as far as possible, the chances of infection.

CONGENITAL DEAFNESS.—Moos ("Arch. of Otol.," xi, 4) found the sexes equally represented in the cases examined, and the age varied between one and seventeen years. In fourteen cases no cause could be assigned; in seven cases hereditary predisposition was present; in ten cases parental consanguinity; in three both hereditary predisposition and parental consanguinity; in one syphilis; in one intemperance of the father; in one premature birth; in one a high degree of scrofulosis of mother and child. Direct heredity existed in no case, while in seven cases an hereditary disposition could be proved. Moos agrees with modern ophthalmologists that almost all chronic parenchymatous inflammatory affections of the cornea, complicated with disturbances of hearing, are of syphilitic nature. He regards rachitis as an important cause of early anatomical alterations in the labyrinth. He agrees with Virchow that brachycephalic and microcephalic skulls, besides defective development of various parts of the brain, occasion also an atrophy of the petrous bone, a cause of the congenital deafness in such cases.

ONE HUNDRED CASES OF AURAL POLYPUS.—Moos and Steinbrügge ("Zeitschrift f. Ohrenheilk.," xii, 1) give some very interesting facts in relation to aural polypi in these cases. The polypi were single in eighty-one cases, multiple in nineteen;

the latter occurred occasionally in the meatus alone, occasionally in the tympanum alone, and six times in both simultaneously. Otorrhoea was absent in only a single case. In all but one case the polypus was deep-seated in the meatus. Not a single polypus sprang from the drum-membrane itself nor from the handle of the hammer. The number of cases in which a relapse was undeniable was eighteen. The shortest interval between the operation and the relapse was one month; the longest, nine years. Ten polypi were accompanied with caries; six of the mastoid process alone; one of the meatus and middle ear simultaneously; one of the labyrinthine wall; one of the pyramid; and one of the meatus, mastoid process, and the pyramid together. Four of the cases were accompanied by cerebral symptoms before the operation. The immediate cause in all of these cases was the hindrance to the outflow of pus by the tumor; when the latter was removed, the cerebral symptoms disappeared. All of the cases of angiomata may be followed by excessive hemorrhage during the operation, or by secondary hemorrhage. The authors think that the term "mucous polypus" must be abandoned, but they adopt the rest of the customary nomenclature, except that they call the common "round-cell polypus" "granulation tumor," and subdivide the fibromata into pure and so-called angio-fibroma. These granulation tumors represent at the same time the transition step in the development of angio-fibromata. The latter term should be strictly reserved for such tumors as are developed from blood-vessels. A tumor with cavernous spaces should not be called an angio-fibroma. Clinically and microscopically, the fibromata are not to be differentiated in any way from the so-called angio-fibromata, but genetically there is a decided difference. The authors found only four myxomata in one hundred cases. Histological extravasations and pigment metamorphosis are frequently observed in aural polypi; they are sometimes circumscribed and sometimes diffuse. The more immediate causes of their origin are: 1. Increased vascularity; 2. Obstruction of the vessels by endothelial proliferation in cases of tumors of rapid growth; 3. Thinness of the vascular walls; 4. Regressive metamorphosis of the stroma and secondary alterations in the tension of the interior of the tumor, especially in the case of central formation of cholesteatomata; 5. Mechanical influences before the operation, or even the operation itself. Neoplastic formation of bone in the polypi was observed in three cases. This neoplasm must be regarded as heteroplasia. Central necrosis was observed in two cases. Formation of cysts was observed in only one case, and in that from the blood-vessels. The authors consider that the operative removal of aural polypi must be undertaken without hesitation: 1. As a matter of life and death, when the symptoms indicate an accumulation of pus; 2. In all cases in which a single polypus, or several of them together, have attained so large a size that they are liable to fill the cavities in which they lie, and to give rise to an accumulation of pus with all its accompanying dangers. Polypi that are not quite large enough to hinder a satisfactory exit of pus may experimentally be treated with remedies, among which they place in the front rank absolute alcohol, or solutions of lead acetate, supersaturated. The galvano-cautery they regard as the very best method of after-treatment to prevent relapses, and for the rapid removal of small tumors that could not be reached with the snare. Also for cauterizing cholesteatomatous masses in the tympanum. Also for producing a stiff cicatricial tissue as free from blood-vessels as possible, in the place of a softened and thickened lining of the tympanic cavity that has undergone epidermoid transformation, and is liable to continue in a chronic inflammatory condition. Also in cases of multiple formation of larger or smaller polypi, whose origin in the deeper-seated portions of the ear is difficult to detect, and in which it

is quite impossible to remove all the roots with the snare. Also in caries with formation of polypi, whenever it is necessary to obtain a satisfactory exit for the pus.

CASCARA SAGRADA IN CONSTIPATION.—J. Fletcher Horne, F. R. C. S., writes: "*Cascara Sagrada*, *Rhamnus purshiana*, is a small tree indigenous to the Pacific coast of North America. The fluid extract I have used is that prepared by Parke, Davis & Co., Detroit, and procurable of their agents, Messrs. Burgoyne, Burdidges & Co., London. Its use, in my hands, seems to be indicated in almost all cases of constipation, particularly in cases of torpidity of the liver, with scanty dry stools and indigestion. It seems to act as a stimulant to the muscular fibers of the intestines, through its action upon the sympathetic nerve, this increasing the vermicular movements of the intestines, thus resembling *nux vomica*. I have used it in several cases of obstinate constipation with very satisfactory results. I generally give twenty drops three times a day in sweetened water for ten days or a fortnight; and then, gradually reducing this dose, the patient is able to establish a habit of regularity. Given in doses of a teaspoonful, it acts as a gentle purgative, without producing any gripping tenesmus or nausea; but its action is slow, and, in this sized dose, seems to lose its good property of curing the constipation. With children, with smaller doses, I have had equally good results."—*British Medical Journal*.

ON PREVENTION OF LACERATION OF THE PERINEUM.—Mr. Alexander Duke, M. K. Q. C. P. I., Obstetric Physician to Dr. Steevens's Hospital, Dublin, remarks: "The best preventive treatment of laceration that I have found (and which I dare not claim as original, though I find no notice of it in the text-books on midwifery) is this: When I find the head fairly engaged in the pelvis, and advancing with each pain, I take my seat by the patient's bedside, and, having lubricated my left thumb, or the two first fingers of my right hand, I introduce either into the vagina, and, at the onset of a pain, draw back the perineum firmly, but gently, toward the coccyx, relaxing the tension gradually as the

pain lessens till the next ensues, and so on till I can draw back the perineum with very slight effort. I thus tire out the muscular structure, and produce sufficient relaxation for the head to pass.

"In most cases so treated there is no danger of the perineum, but when the pubic arch is narrow (which can be easily determined), I take the additional precaution of raising the patient's left hip and supporting it on a hard pillow, while the shoulders are kept low, fomenting the parts, using inunction of lard or vaselin, and taking particular care to direct the head forward by pressure, with my left hand below the coccyx, or a finger in the rectum, leaving the perineum untouched. It has always seemed anomalous to me that the perineum should be expected to dilate on such short notice, namely, 'the process of extension,' while dilatation of the os and cervix occupies such a considerable time, even with the additional help of nature's hydrostatic dilator, viz., the bag of waters.

"The drawing back of the perineum produces no additional pain to the patient, as it is done during a uterine contraction; and I feel sure that, if nurses and students were educated as to the proper way of preparing the perineum previous to its distension with the presenting part, we should see and hear less of lacerated perineum."—*British Medical Journal*.

PRACTICAL PATHOLOGICAL WORK.—Mr. H. A. Reeves, F. R. C. S., Assistant Surgeon to the London Hospital, draws attention to the triple and double staining of tissues and tumors for microscopical purposes. He mentions several new coloring agents. "The new dyes are phloxin and erythrosin. I do not yet know their exact composition, but feel almost sure they are obtained from resorcin, as in many physical and chemical respects they resemble rosin. They stain rapidly and deeply, in weak aqueous solutions, and stand spirit well. Connective substances and the protoplasm of cells are, in rapid staining, preferred by them to nuclei, which, however, stand out on the stained ground-work very clearly. Phloxin is the more beautiful and pleasant color to work with. Both are soluble in water or spirit, and weak solutions stain quickly. If sections be placed in weak solutions for several hours, the nuclei often take on the stain. Phloxin and erythrosin, as supplied to me, are darkish red powders by reflected light, the former having a faint purplish-crimson color, and the color of the solutions in a test tube, i. e., in transmitted light, will vary according to the strength. Any of the dyes herein mentioned may be obtained direct from the agent of the Badische Anilin Fabrik, 22 Bush Lane, E. C., or from Messrs. Wright, Layman & Umney, or in small quantities from Mr. Cooper, chemist, Oxford Street, W. Messrs. Brooks, Simpson & Spiller, Broad Street, E. C., also keep several of them. Murexide has—so far as I have been able to find—not yet been used in microscopy. It is given up by the dyers in favor of rosanilin, and is consequently not in demand, and therefore not easily procured. It is a brownish-red powder, and very slightly soluble in cold water, not soluble in spirit, but readily soluble in boiling water. On cooling and filtering, the sections are immersed for five or ten minutes, when it will be found to furnish a good ground stain for double dyeing. With acetate of zinc, murexide gives a yellow stain. Maroon, phosphine, cerise, and mauve are all useful and unused colors, phosphine yielding a good ground stain of a rich golden yellow, and may be used with advantage in double staining. The rest resemble most of the other anilines in picking out the nuclei, but they also stain the other structures. Dilute aqueous or alcoholic solutions stain rapidly, and may be fixed. Induline is also a new aniline color, and may be used as above. It is a dark powder, and gives an agreeable pale-bluish purple stain; and, if used after carmine or picramine, the cell-body and intercellular substance will be preferred by the induline, and the nuclei connective fibers by the others. It dissolves in warm water or dilute alcohol." For triple staining, Mr. Reeves has had the best results when using methylanilin, violet and iodine, and malachite or methyl green combined. For double staining he employs rosine and green.—*British Medical Journal*.

A NOVEL AGENT IN THE RADICAL CURE OF HYDROCELE.—J. E. W. Walker, M. R. C. S. E., L. S. A., late H. M. Fifty-fifth Regiment, writes: "In bringing this matter before the profession, I feel bound to admit that, but for a curious accidental circumstance, the agent might never

have presented itself to my notice. In the year 1875 I proposed to operate upon a patient, aged sixty-five, for the radical cure of hydrocele of the tunica vaginalis. The disease had existed for about ten years, and had been repeatedly emptied by other surgeons. At this time I removed, by the trocar and cannula, about twelve ounces of serum, and, by accident, took from my pocket a bottle containing about two drachms of liquor ergotæ (Battley) in the place of the same quantity of tincture of iodine, which it was my intention to throw into the cavity. On my return home, I discovered the mistake, and watched the patient for some hours at intervals. No inflammatory state occurred, and there was entire absence of pain, so that I allowed my patient to re-
turn to his ordinary occupation the next morning. To the present time there has been no return of the abnormal secretion. I have since, on two occasions, used the same plan with perfect success, and I attribute the cure to a specific action, exerted by ergot, which re-establishes the balance between secretion and absorption."—*British Medical Journal*.

PICRIC ACID IN ERYSIPELAS.—Dr. Flaminio Tassi, of Siena, has used a saturated solution of picric acid in the treatment of four cases of erysipelas. It was painted on with a brush over the inflamed part. It appears to have a beneficial action, but the number of cases is too small to enable any definite opinion as to its therapeutical value to be formed as yet.—*Practitioner*.

EMERGENCY LECTURES IN BOSTON.—It is announced by a correspondent of the "Boston Medical and Surgical Journal" that a course of "emergency lectures" is soon to be given in that city, "for gentlemen only." Among the emergencies mentioned by the writer are "singultus, delirium tremens, alcoholic coma, orchitis, adenitis, cystitis, retention, and catheterization"!

THE BOSTON SOCIETY FOR MEDICAL OBSERVATION.—At the annual meeting, held April 2, 1883, the following gentlemen were elected officers; Secretary, Dr. C. H. Williams; Treasurer, Dr. C. M. Green; Librarian, Dr. George Stedman; Pamphlet Librarian, Dr. W. J. Otis; Committee on Admission, Dr. W. L. Richardson, Dr. F. C. Shattuck, Dr. A. T. Cabot, and Dr. C. H. Williams *ex officio*.

THE LONDON WATER SUPPLY.—In a recent number of the "British Medical Journal" Dr. Percy F. Frankland remarks, with regard to a table showing the proportion of organic impurity present in Thames water, as delivered in London year by year from 1868 to 1881: "This table clearly and irresistibly attests the general deterioration which has taken place in the average quality of the Thames water delivered in London. It must further be borne in mind that this deterioration has gone on in spite of both greater storage capacity and much improved filtration on the part of the companies. What is here stated of the Thames applies equally, but in a less degree, to the water of the Lea. Since this, then, is the condition of the water which the companies have the monopoly to purvey, too much caution can not be exercised in accepting the wholly unofficial reports which are now made in the interests of the water companies, and which are calculated to allay the just cause of dissatisfaction excited by the official and impartial examination made by the Local Government Board in the interests of the public. It should not be forgotten that, even when their supplies were drawn from the grossly polluted lower Thames, the water companies were able to procure from scientific experts reports of the perfect wholesomeness and unimpeachable purity of their water. Thus, reporting to the Southwark Company upon the quality of Thames water between Teddington and Chelsea, three chemists pronounced the water to be 'as perfectly harmless as any spring water of the purest kind used in common life; indeed, there is probably not a spring, with the exception of Malvern and one or two more, which is so pure as the Thames water.' Again, at a more recent date, the Thames water at Battersea, then in close proximity to the sewer outfall, was described as 'good, wholesome, and proper, free from any noxious impregnation of animal matter, and well adapted to dietetic, domestic, and manufacturing uses. Until the year 1862, the inhabitants of London were content, or rather compelled, to drink the water of the Thames drawn from the river opposite Hungerford Market, and all legislation intended to alter the then existing state of things was strenuously opposed by

the water companies. The consternation caused by the terrible epidemic of cholera in 1849 so aroused public opinion that an alteration of the source of supply was insisted upon. It is to be hoped that the public will not require an equally severe lesson before they insist that the Thames and the Lea shall be altogether abandoned for the purpose of furnishing water to London, and that the day may not be far distant when the whole of the metropolis shall enjoy a supply of water as pure as that which is now given to a limited portion of the southeastern district only."

NOTWITHSTANDING all the touching and beautiful talk in the New York County and State medical societies in regard to the matter of "humanity" and the "elevation of the standing of the profession," it would at first sight seem rather a significant fact that the new code agitation was entirely inaugurated by specialists, and that every man who has taken at all an active part in securing its adoption and preventing its repeal is a specialist. It is probably, however, only a curious coincidence that the specialists are the ones who must necessarily derive the largest amount of pecuniary benefit from consulting with all "legally qualified practitioners of medicine." Among legally qualified practitioners our new code friends in New York will, no doubt, be much pleased to learn that they may now have the opportunity of meeting in consultation the noble and good Dr. Buchanan, lately of Philadelphia, who, we are informed on excellent authority, is now a registered physician in their city, and who, having graduated from Moynessing, as well as a medical college, must have had special opportunities of study and experience, which the profession and public ought not to be slow in availing themselves of. There is one point, involving to some extent the matter of consistency, which the ordinary Philistine medical mind is not quite capable of satisfactorily comprehending. How is it that the very gentlemen who are the most energetic and persistent supporters of the new code are also those who are most clamorous for the higher education of the profession, and are the leaders in establishing innumerable post-graduate courses to this end in every department of medicine and surgery, when by this same new code any Tom, Dick, or Harry who can buy, steal, or study six weeks for a diploma is placed on the same level as a graduate of Harvard or the University of Pennsylvania, who has spent a couple of years or more in the hospitals after receiving his degree?—*Boston Medical and Surgical Journal*.

THE University of Aberdeen lately conferred the degree of LL. D. on R. Farquharson, M. D., and James Ross, M. D.

THE second congress of the Gesellschaft für innere Medizin will be held at Wiesbaden on April 17th.

A TESTIMONIAL TO MR. ERICHSEN.—A bust of Mr. John Eric Erichsen was recently presented to University College, London, at a large public meeting held in the botanical theatre of the college, as a memorial of Mr. Erichsen's services to the college and to surgery.

A COLLEGE OF MIDWIFERY.—Under this name a school has been started in New York for the instruction of midwives. Each session comprises a three months' course, four evening lectures being given each week, in addition to demonstrations, recitations, and bedside teaching. The faculty consists of Dr. Paul F. Mundé and Dr. Benjamin F. Dawson, censors, and Dr. James O'Reilly, Dr. John Alsford, Dr. Thomas H. Wilcox, and Dr. Jacob Hartmann, instructors. A diploma is to be given after satisfactory examination.

THE OLEATES.—Oleates are not to be mixed with vasoline or any petroleum products, as the latter are not absorbed by the skin and retard the action of the oleates. Mineral fats have no affinity for animal tissues, while lard and other animal fats are rapidly absorbed by the skin of the human body.—*Weekly Medical Review*.

A GOVERNMENT EXPERIMENTAL LABORATORY.—The newspapers announce that the Department of Agriculture has leased a piece of ground in the neighborhood of Washington for the purpose of establishing a laboratory for the experimental investigation of the infectious diseases of domestic animals.

INTERFERENCE WITH THE HEALTH LAWS.—A bill is said to have been brought before the State Legislature, the intent of which is to prohibit

Boards of Health from forbidding the use of tile pipes in making sewer connections. It is now discretionary with such boards to allow or prevent the use of pipes of that material, according to the circumstances of individual cases, and any attempt to hamper the exercise of such discretion on the part of sanitary authorities should meet with vigorous opposition.

A NEW GERMAN DISPENSARY.—A new dispensary has been organized, as an additional means of meeting the wants of the leased German population of the eastern part of New York. It is expected that the work of the new dispensary will begin about the 1st of May. Among the physicians who are connected with the institution are Dr. F. W. Lilienthal, Dr. C. A. von Ramdohr, Dr. G. W. Rachel, Dr. R. O. Born, Dr. W. C. Ayres, Dr. G. C. Stiebling, Dr. J. H. Tyndale, Dr. S. Kohn, and Dr. C. E. Denhard. It is understood that the dispensary will be established at No. 411 Sixth Street.

JEFFERSON MEDICAL COLLEGE.—The annual commencement of the Jefferson Medical College, of Philadelphia, was held on Monday last. The graduating class is stated to have numbered nearly two hundred.

PERSONAL ITEMS.—Dr. L. T. Day, for the past year house physician at the New Haven Hospital, has resigned, and will be succeeded by Dr. Gillon, a graduate from the University Medical College of this city. — Dr. Taylor, formerly of the Pennsylvania Hospital, has been appointed resident surgeon of the University Hospital, Philadelphia, for the month of April.

DEATH OF DR. D. O. FARRAND, OF DETROIT.—Twenty years ago Dr. Farrand, then an undergraduate, was known to his fellow-pupils at the College of Physicians and Surgeons, in this city, as one of the most promising and estimable of their number. After taking his degree, he entered the medical corps of the army, in which he served until 1866, when he began private practice in Detroit. His career in that city has been in the highest degree creditable, and we are glad to learn, peculiarly successful. We are pained at the intelligence that he died, on the 18th ult., of a meningeal affection following an attack of otitis.

DEATH OF DR. NATHANIEL LOW.—Dr. Nathaniel Low, of Dover, N. H., died on the 2d instant, at the family residence, Bellamy, two miles from the city, at the age of eighty-one. Dr. Low was graduated from Dartmouth Medical College in 1813, and began the practice of his profession in South Berwick, Me., his native place. In 1831, after six years of political life, he settled in Dover, where he practiced until his last illness, which was somewhat protracted. He was a Fellow of the New Hampshire State Medical Society and a member of the Strafford District Medical Society.

DEATH OF SURGEON JOSEPH H. BAILEY, U. S. A.—Surgeon Joseph H. Bailey, U. S. Army (retired), died last Sunday at Kent Cliffs, Putnam County, N. Y., in his eightieth year. Dr. Bailey was a native of this State, from which he was appointed to the medical corps of the army in 1834. He attained the rank of captain in 1839, and was retired in 1862.

THE LATE SURGEON KEENEY, U. S. A.—A recent number of the San Francisco "Evening Bulletin" contains the following tribute to the memory of this officer, written by Colonel Mendell, of the engineers: "By the death of Surgeon C. C. Keeney the army and the country are deprived of the services of one of their most valuable officers. In intellect and in physical qualities, which are essential to afford a field of action for the intellect, he was, until his prostration by disease, the peer of any and all. Entering the service in 1842, he passed through all the grades of the medical corps, holding at his death the commission of colonel. In forty years of duty he never asked for or received the indulgence of a leave of absence. He served professionally through the Mexican war, from its beginning to the end, leaving Mexico after peace was declared. During the great civil war he served in the first campaigns of the Army of the Potomac, and afterward in organizing and in inspecting hospitals in and about Washington and over the upper Mississippi Valley. He was forced to relinquish this duty by an attack of total blindness, induced by the exposure and unremitting labor incident to his work. This attack confined him to a dark room in

Chicago for six months, with little or no improvement in his condition. Pronounced by a board of surgeons to be in a hopeless condition, he returned to his home in San Francisco, himself the only one confident of a recovery. This recovery occurred, and, if a physical change ever results from a resolute and faithful condition of mind in the patient, his recovery may have been in part due to the strength of his character. Since 1864 he has been stationed in this city, attached to the headquarters of the department, of which he was long, and at the time of his death, Medical Director, having previously been for some years attending surgeon. Those who had the benefit of his attentions in the latter capacity can never forget the quick perception which diagnosed a disease, and the professional intelligence and knowledge which alleviated suffering. His conscientious attention to the needs of the sick will long be gratefully remembered by those who were its recipients. He was full of military spirit and pride in the service. Nothing that concerned the interests of the army was indifferent to him. His hours of recreation were passed in literary pursuits. Those who were familiarly admitted to his home were accustomed to find him in leisure hours in his library, where he was surrounded by a choice selection of books, covering the fields of literature, history, and science."

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 24, 1883, to March 31, 1883.*—BARNETT, RICHARDS, Captain and Assistant Surgeon. To proceed to Fort Adams, Rhode Island, and report to the commanding officer for duty at that post. Par. 1, S. O. 51, Department of the East, March 28, 1883. — CRONKHITE, HENRY M., Captain and Assistant Surgeon. Relieved from duty at Fort McKinney, Wyoming Territory, and assigned to duty as Post Surgeon at Fort Fred Steele, Wyoming Territory. S. O. 31, Department of the Platte, March 22, 1883. — DE LOFFIE, AUGUSTUS A., Captain and Assistant Surgeon. Granted leave of absence for three months. Par. 3, S. O. 71, A. G. O., March 27, 1883. — LORING, L. Y., Captain and Assistant Surgeon. To proceed without delay to Fort Schuyler, New York Harbor, and report to the commanding officer for duty as Post Surgeon. Par. 2, S. O. 51, Department of the East, March 28, 1883. — MOSELEY, EDWARD B., Captain and Assistant Surgeon. To report in person to the president of the Army Medical Examining Board in New York City for examination for promotion, and, upon completion, to return to proper station. Par. 3, S. O. 70, A. G. O., March 26, 1883. — PAULDING, H. O., Captain and Assistant Surgeon. Relieved from duty at Fort Laramie, Wyoming Territory, and assigned to duty at Fort Sydney, Nebraska. S. O. 31, Department of the Platte, March 22, 1883. — SKINNER, JOHN O., Captain and Assistant Surgeon. To report in person to the president of the Army Medical Examining Board in New York City for examination for promotion, and, upon completion, to return to proper station. Par. 3, S. O. 70, A. G. O., March 26, 1883. — TAYLOR, MARCUS E., Captain and Assistant Surgeon. To report in person to the president of the Army Medical Examining Board in New York City for examination for promotion, and, upon completion, to return to proper station. Par. 3, S. O. 70, A. G. O., March 26, 1883. — TURRILL, HENRY S., Captain and Assistant Surgeon. Relieved from duty at Fort Fred Steele, Wyoming Territory, and assigned to duty as Post Surgeon at Fort McKinney, Wyoming Territory. S. O. 31, Department of the Platte, March 22, 1883.

NAVAL INTELLIGENCE.—Passed Assistant Surgeon W. H. Crawford has been ordered to the Pinta, which vessel, after being inspected at Hampton Roads, will proceed to Alaska, touching at San Francisco. — Passed Assistant Surgeon F. H. Terrell has been granted leave of absence for one year from April 1st. — Six months' sick leave has been granted to Surgeon John W. Coles. — Passed Assistant Surgeon B. F. Rogers has been detached from the Richmond, of the Asiatic squadron, and ordered temporarily to the Monocacy, which left Nagasaki January 31st for Amoy. — For the foregoing items we are indebted to the "Army and Navy Journal." — The Naval Medical Board, consisting of Medical Director F. M. Gunnell, Medical Director W. J. Hood, and Medical Inspector David Kindelberger, held its first meeting at the Navy Department, in Washington, on the 2d instant.

Lectures and Addresses.

WILLIAM HOLME VAN BUREN, M. D.,
LL. D. (YALE).

A MEMORIAL ADDRESS,

READ BEFORE THE NEW YORK ACADEMY OF MEDICINE, APRIL
5, 1883.

By EDWARD L. KEYES, M. D.

MR. PRESIDENT AND FELLOWS OF THE ACADEMY: I am here in response to your request to address to you to-night some words in memory of your late associate, my dead friend and master, Dr. Van Buren.

I accept the task with hesitancy, fearing lest my poor powers should prove inadequate to detail his worth, or that my zeal may lead me into such personal expressions of admiration as may fail to be appreciated by or acceptable to those among you who have known him less well than I. For he was to me a kind father, a patient guide, directing my uncertain efforts from the first day I entered the paths of medical investigation. I did what I could in return by sustaining his faltering footsteps as they tottered toward the tomb. And the spirit in which I attempt to perform this last office in his honor must atone for all defects in its execution.

"May the sod rest lightly over him."

William H. Van Buren, M. D., LL. D. (Yale), upon the morning of the 25th of March, 1883, terminated a career of no ordinary brilliancy, and left a place in the ranks of the medical profession which will probably long remain unfilled.

Born in Philadelphia, April 5, 1819, to-day is the anniversary of his appearance on earth. At his death he had not completed his sixty-fourth year. He died, as he lived, gracefully, in no unbecoming haste, with entire dignity. He delivered his last lecture to the class at the Bellevue Hospital Medical College on the 6th of December, 1882, a little more than three months before his death, and during these three months his failure was so gradual that those who watched at his bedside found difficulty in deciding at just what moments the changes came, although the general deterioration was constantly evident.

During the mild delirium of fever incident to the inflammatory process taking place about the clot in his brain, he was never little, never rude, never vulgar. Courtesy and dignity marked his last utterances. He died, as he lived, a gentleman. The burden of the delirious wanderings of his mind, as expressed in his speech, was a desire to get away, to go somewhere. He finally started on the expected journey on Good Friday evening, and from that moment until the journey ended, on Easter morning, his body and mind were in perfect peace.

Although cut off before finishing the natural period allowed to man, he had improved his opportunities, and he left behind him a reputation surpassed by no one for high refinement as a gentleman, classical polish as a scholar, unequaled grace as an operator, clearness, force, elegance as a

lecturer, profound judgment as a physician. He has left his mark upon the profession he adorned, and has elevated its tone and its dignity by his uncompromising exaction of respect for the science and art in which he dealt—a respect which he insisted upon from all who approached him in his consulting-room or elsewhere.

He doubtless inherited a fondness for medical research from two of his ancestors, his grandfather and great-grandfather, both of whom were physicians.

His entire education up to graduation was conducted in Philadelphia, the city of his birth, with the exception of something more than two years passed at Yale College. He entered that institution with the class of 1838, but during Junior year, on account of some boisterous demonstrations to which he was a party, the college saw fit to drop him from the rolls. Yet that this incident did not obscure his merits from the appreciation of the Faculty is evidenced by the fact that the same institution tendered him, in 1866, the academic degree A. M., and in 1878 decorated him with its highest honorary title, LL. D., thus recognizing his prominent position in the community and his scholarly attainments.

After leaving Yale, he entered the medical class of the University of Pennsylvania, and finished his studies there before reaching the age at which graduation was allowable. Before graduating, therefore, he went to Paris with Dr. Harlan, of Philadelphia, and remained in that city at his medical studies for eighteen months. During his Parisian student days he formed a warm attachment for Gueneau de Mussy, which endured through life. He served on the house staff in La Charité Hospital under the great Velpeau. In Paris he first met the late Valentine Mott, who afterward became his father-in-law.

Returning to America, he graduated in medicine from the University of Pennsylvania in 1840, choosing as the subject of his thesis of graduation the starch and dextrin bandage, a knowledge of which he had brought home from Paris. Thus early in his career did he manifest his mental scope in recognizing the value of the immovable apparatus many years before its worth was generally appreciated by the profession.

This essay possessed such evident merit that the Faculty took charge of its publication (an unusual honor), and appointed a time and place where the young doctor should give a public demonstration of the application of the bandage. This was done by Dr. Van Buren, the assemblage addressed being, as he has recently stated, the largest professional gathering before which he ever appeared.

After graduation, Van Buren entered the army, passing first in a competitive examination, and thus ranking the late Surgeon-General Joseph K. Barnes (whose death to-day is announced in the evening papers), and who passed with him, so that, had he remained in the Government service, it is fair to believe that he would have reached the highest medical position in its gift. Indeed, this position was offered him during the war by Lincoln, but for various reasons declined, whereupon he was asked to name a candidate.

He served in the army under Generals Wool and Har-

ney in Florida, and for a short time on the Canadian border. In Florida his health broke down under intense malarial poisoning, and the seeds of certain physical disabilities were sown from the effects of which he never entirely recovered. In 1844 he was stationed in the meteorological department at Washington under Surgeon-General Lawson.

In 1845 he came to New York to assume the duties of prosector to the chair of surgery in the medical department of the University of New York under Dr. Valentine Mott.

In this medical school he remained doing active duty as an organizer and operator in the Mott Clinic, and, after the year 1852, as professor of anatomy, a position which he retained until the burning of the college building in Fourteenth Street in 1865. In this fire was burned his valuable collection (of plates, instruments, and specimens) appertaining to the anatomical chair.

After this disaster Dr. Van Buren declined to go on with the school unless the professorial staff was reorganized (he desired to change his anatomical for surgical teaching), and unless a fine building was erected in East Twenty-sixth Street, opposite and in competition with the already flourishing Bellevue Hospital Medical College, and capable of enjoying like privileges in the Bellevue Hospital. These counsels—at a later period adopted in all their essential features—were disregarded at the time, and Dr. Van Buren resigned.

In 1868 he was elected to a professorship in the Bellevue Hospital Medical College, and as professor of the science and art of surgery in that institution he lectured up to within a few months of his death.

He was appointed one of the surgeons to the Bellevue Hospital at its organization in 1847, and in 1852 was made surgeon, and afterward consulting surgeon, to the New York Hospital. Later he became surgeon, and then consulting surgeon, to St. Vincent's Hospital, and consulting surgeon to the State Woman's, the Charity, and the Presbyterian Hospitals. Among the positions of honor which he filled may be mentioned the vice-presidency of the New York Academy of Medicine in 1859, the presidency of the Pathological Society, and the position of consulting surgeon to a great number of the most prominent organized medical charities in the city. In 1867 he was elected corresponding member of the Société de Chirurgie of Paris, an honor up to that date conferred upon only one other American. In 1879 he was one of a few surgeons who organized the New York Surgical Society.

Early in his professional life he began to turn his attention toward writing. In 1854 he translated Morel's "Histology," showing at that early date his keen appreciation of the needs of surgery, and its dependence, in a prognostic way at least, upon histological research. His next effort was the translation of Bernard and Huette's "Operative Surgery," a work which was furnished by the United States Government to the army surgeons during the late war.

In 1865 he published some surgical essays in book form as "Contributions to Practical Surgery," one of these essays relating to a successful case of ovariectomy, which he performed during the days when this operation was almost in

its infancy, and before it had been absorbed into the domain of gynecological specialism.

His lectures on "Diseases of the Rectum" appeared in book form in 1870, a second and much ampler edition of the same work in 1882. In 1874 he appeared jointly with his junior associate in a text-book on "Genito-Urinary Surgery."

In 1876 he read an able article on "Aneurysm" before the International Medical Congress assembled in Philadelphia, while his most recent essay on "Inflammation," in Ashhurst's "International Encyclopædia of Surgery" in 1881, is one of the ablest efforts which have appeared in print from his pen.

Up to the time of his death he had in contemplation and preparation a series of essays on the "Principles of Surgery," which he hoped to complete and give to the world.

During his entire medical life he frequently appeared in the medical periodicals of the day in essays on surgical subjects, marked by their practical character, the weight of the lesson they enforced, and their terseness, as well as elegance of expression.

During his early professional life he was a zealous and active surgeon in all general branches. He was particularly attentive to hospital and clinical duties, to medical teaching and medical society work. His name is attached to a special mode of amputating at the hip joint, and many general surgical operations have received useful modifications at his hands, while a few instruments bear his name.

As his professional success rendered necessary a selection of the kind of work he should do, he gradually came to identify himself with genito-urinary and rectal surgery, falling into these channels partly from inclination and partly by opportunity. He never considered himself a specialist, on the whole rather resenting the idea, preferring to rank as a general surgeon. His perfection of certain urethral instruments remains as one of his triumphs.

His connection with the Sanitary Commission, of which he was one of the founders, is a matter of history. He served faithfully on the executive committee of this organization during the war, and added largely to its efficiency by his ability as an organizer and his power of getting good work out of those under his orders. It was during the performance of duties connected with this commission that he acquired typhus fever, a malady which nearly terminated his career in 1864 before he was fairly ripe.

From the shock of this malady, followed as it shortly was by the death of his only son, he never fully rallied in energy and nervous vigor. While his judgment remained unimpaired and his intellectual qualities improved, his desire for active physical work diminished at a continuous pace until the year of his death. His chief delight became the study of trees and flowers and the perfection of his country place at Shrewsbury, where he spent half of each week, winter and summer.

In 1842 he married Louisa, daughter of the late Valentine Mott, who, with two married daughters, survives him.

Dr. Van Buren was a man full of force, full of kindness, but a martyr to the gout. As a master, he was at times ex-

acting, but always just; as a friend, he was surpassed by none. When found overworked, particularly if the gout was upon him, he was apt to be considered haughty and imperious; but his gentleness and refinement were always obvious to those who knew him best, shining out through the mists of any atmosphere in which he was pleased temporarily to shroud himself.

He was unswerving in his demands upon the respect of those about him, and in all his actions, public or private, the elements in his character which were most marked were those of breadth and grandeur. Littleness and meanness were not to be found in his composition. His friends loved, his enemies feared him; all respected, all admired him. He was deliberate in the selection of those whom he should trust, but his confidence once given was final, his trust was "all in all or not at all," and his judgment in the choice of friends was not often at fault.

Dignity and grace vied with each other to find expression in his commanding figure—a figure rendered all the more imposing by his military training. The charm of his personal presence was equally apparent under all circumstances before men singly or collectively. The gravity of his counsel and weight of his judgment were most prized by his peers in consultation. The patient welcomed his coming with gladness, and without a murmur, in that entire confidence born of faith, yielded into his hands the issues of life and of death.

The same personal magnetism was evident in his intercourse with students. Who can forget the swing of his supple figure as he entered the lecture-room of the old University in the glorious days of his pride, and the princely bow with which he saluted his class as the dome of the amphitheatre resounded in responsive echo to their acclamations of appreciative reception. His later efforts at Bellevue were none the less gracious, and his white head and beard and the motions of his heavier frame made up in dignity what they lacked in fire.

No more touching evidence of the hold he maintained upon those who had once felt his influence could have been offered than the mute eloquence of the tears of his old servants of by-gone years as they crowded about his remains for a last look at him whom they had loved.

Born a Protestant, he became a Roman Catholic by conviction early in his professional life, and for many years before his death he was devout in his observance of the duties imposed by that Church. Comforted by all the consolations the Church could afford, and fortified by its last sacred rites, in the calm glory of the Easter dawn his soul sought eternity—fit occasion for such a flight. Without a struggle he passed peacefully away; and let us from this scientific altar join our prayer to those already pronounced by the Church over his remains, in the aspiration that his grand old soul, through the mercy of God, may rest in peace.

BELLEVUE HOSPITAL MEDICAL COLLEGE.—At the annual meeting of the Faculty of the Bellevue Hospital Medical College, held April 8, 1883, Dr. Frederic S. Dennis was appointed Professor of Principles and Practice of Surgery and Clinical Surgery to fill the vacancy caused by the death of the late Professor Van Buren.

MEDICAL ETHICS AND ETIQUETTE.

COMMENTARIES ON THE NATIONAL CODE OF ETHICS.

By AUSTIN FLINT, M. D.

Fifth Article.

SECTION 8. Should an irreconcilable diversity of opinion occur when several physicians are called upon to consult together, the opinion of the majority should be considered as decisive; but if the numbers be equal on each side, then the decision should rest with the attending physician. It may, moreover, sometimes happen that two physicians can not agree in their views of the nature of a case and the treatment to be pursued. This is a circumstance much to be deplored, and should always be avoided, if possible, by mutual concessions, as far as they can be justified by a conscientious regard for the dictates of judgment. But, in the event of its occurrence, a third physician should, if practicable, be called to act as umpire; and, if circumstances prevent the adoption of this course, it must be left to the patient to select the physician in whom he is most willing to confide. But, as every physician relies upon the rectitude of his judgment, he should, when left in the minority, politely and consistently retire from any further deliberation in the consultation, or participation in the management of the case.

SECTION 9. As circumstances sometimes occur to render a special consultation desirable, when the continued attendance of two physicians might be objectionable to the patient, the member of the faculty whose assistance is required in such cases should sedulously guard against all future unsolicited attendance. As such consultations require an extraordinary portion both of time and attention, at least a double honorarium may be reasonably expected.

The disagreement of doctors has long been proverbial. Without entering into any discussion of the grounds for the popular impression that physicians are more apt to disagree than those engaged in other pursuits, it is certain that in medical consultations a diversity of opinions calling for the measures which are enjoined in the ethical code is extremely rare. The writer of these commentaries, during a long experience, has known of but very few instances. In the event of a diversity of opinion relating to the nature of the case and the treatment to be pursued, the "good of the patient" is generally better consulted by mutual concessions than by resorting to the measures just alluded to. The concessions should be mutual; that is, neither the attending nor the consulting physician has a right to expect that on his side nothing is to be conceded. The consulting physician is to consider that the attending physician has had the advantage of having observed the case from the commencement, and generally, also, of a better acquaintance with the previous history of the patient. On the other hand, it often happens that the attending physician is bound to recognize a larger experience on the side of the consulting physician, and, perhaps, the advantage of his having given special study to the disease from which the patient suffers. These are grounds for concession on either side. If, however, a diversity of opinion be so great as not to be reconciled by mutual concessions, to agree seemingly, but not in

reality, would plainly be in violation of truth and justice. The measures inculcated by the code, under these circumstances, must commend themselves as proper, in view of the feelings and interests of all concerned.

Whether consultations are to be repeated or not, and how frequently they are to be repeated, should be determined by the circumstances in particular cases. When desired by patients or their friends, it is unwise for the physician in charge to oppose their repetition on the ground that they are not necessary. Whether necessary or not, patients or their friends are entitled to have their wishes gratified in this regard, especially if the additional expense be understood. If their wishes be thwarted by the physician in charge, he may afterward have occasion for regrets. The consulting physician has his rights in this matter, inasmuch as he has assumed a part of the responsibility of the case. It is not, therefore, improper for him, in certain cases, to request additional consultations. On the other hand, he may be invited to repeat the consultation merely as an expression of politeness or respect, and it may be becoming in him to say that he considers a repetition unnecessary. In general, the propriety of the rule respecting "unsolicited attendance" is sufficiently obvious. The exceptional instances are those in which the consulting physician feels unwilling to assume a share of the responsibility without further observation, and those in which he has reason to believe that the limited means of the patient constitute the sole ground for not soliciting a continuance of his services.

There are some points relating to the ethics and etiquette of consultations which are not touched upon in the code. One of these is the duty of a consulting physician who may be asked to take the place of the attending physician in a case while it is in progress. It may happen that there is dissatisfaction with the services of the attending physician, of which the consulting physician may not have been aware, and it is proposed that the former relinquish the case into the hands of the latter. This transfer of a case is justifiable on but one ground—namely, that it is in accordance with the wishes of the attending physician. The consulting physician should satisfy himself on this score. It is not enough that the attending physician consent. He will, of course, do so if requested. If not in accordance with his wishes, the transfer should be positively declined by the consulting physician.

Another point relates to subsequent attendance by the consulting physician. After a case is ended, in another illness the patient may request his services as an attending physician. There may be exceptional instances, but, as a rule, such a request should be declined. If acceded to, it should be after a full understanding with the physician previously in attendance. This and the preceding rule are essential in order that consultations may be held without risk of injury to the feelings and interests of attending physicians. A physician in consultation, if actuated by proper delicacy and a sense of honor, will, of course, sedulously guard against the possibility of his services being preferred to those of the attending physician.

Another point may be referred to. It sometimes hap-

pens that a change of an attending physician is made while another physician is associated in consultation. Shall the latter remain in consultation with the successor of the former? As a rule, certainly not. If the change has been made on account of dissatisfaction with the medical treatment, the consulting physician is as responsible for this as the attending physician, and he should decline to remain in consultation. If other reasons have led to the change, there are obligations of courtesy which are not to be ignored. There should be a full understanding with the attending physician who is superseded. The "good of the patient" is, of course, a primary consideration. The action must be determined by the circumstances proper to each case.

There may be circumstances which should properly lead a consulting physician to decline further association with an attending physician, although no disagreement in consultation had occurred. If the attending physician fail to carry out measures agreed upon, either intentionally or from inefficiency, it is not just for the consulting physician to be held to an equal responsibility in the case. It is the duty of an attending physician to carry out faithfully the course of treatment decided upon, and, if he persistently fail in so doing, the consulting physician is justified in declining to be longer associated with him.

ART. V.—*Duties of Physicians in Cases of Interference.*

SECTION 1. Medicine is a liberal profession, and those admitted into its ranks should found their expectations of practice upon the extent of their qualifications, not on intrigue or artifice.

SECTION 2. A physician, in his intercourse with a patient under the care of another practitioner, should observe the strictest caution and reserve. No meddling inquiries should be made—no disingenuous hints given relative to the nature and treatment of his disorder; nor any course of conduct pursued that may directly or indirectly tend to diminish the trust reposed in the physician employed.

SECTION 3. The same circumspection and reserve should be observed when, from motives of business or friendship, a physician is prompted to visit an individual who is under the direction of another practitioner. Indeed, such visits should be avoided, except under peculiar circumstances; and, when they are made, no particular inquiries should be instituted relative to the nature of the disease or the remedies employed, but the topics of conversation should be as foreign to the case as circumstances will admit.

SECTION 4. A physician ought not to take charge of or prescribe for a patient who has recently been under the care of another member of the faculty in the same illness, except in cases of sudden emergency, or in consultation with the physician previously in attendance, or when the latter has relinquished the case, or been regularly notified that his services are no longer desired. Under such circumstances, no unjust and illiberal insinuations should be thrown out in relation to the conduct or practice previously pursued, which should be justified as far as candor and regard for truth and probity will permit; for it often happens that patients become dissatisfied when they do not experience immediate relief, and, as many diseases are naturally protracted, the want of success, in the first stage of treatment, affords no evidence of a lack of professional knowledge and skill.

SECTION 5. When a physician is called to an urgent case, because the family attendant is not at hand, he ought, unless his

assistance in consultation be desired, to resign the care of the patient to the latter immediately on his arrival.

SECTION 6. It often happens in cases of sudden illness, or of recent accidents and injuries, owing to the alarm and anxiety of friends, that a number of physicians are simultaneously sent for. Under these circumstances, courtesy should assign the patient to the first who arrives, who should select from those present any additional assistance that he may deem necessary. In all such cases, however, the practitioner who officiates should request the family physician, if there be one, to be called, and, unless his further attendance be requested, should resign the case to the latter on his arrival.

SECTION 7. When a physician is called to the patient of another practitioner, in consequence of the sickness or absence of the latter, he ought, on the return or recovery of the regular attendant, and with the consent of the patient, to surrender the case.

[The expression, "patient of another practitioner," is understood to mean a patient who may have been under the charge of another practitioner at the time of the attack of sickness, or departure from home of the latter, or who may have called for his attendance during his absence or sickness, or in any other manner given it to be understood that he regarded the said physician as his regular medical attendant.]

SECTION 8. A physician, when visiting a sick person in the country, may be desired to see a neighboring patient who is under the regular direction of another physician, in consequence of some sudden change or aggravation of symptoms. The conduct to be pursued on such an occasion is to give advice adapted to present circumstances; to interfere no further than is absolutely necessary with the general plan of treatment; to assume no future direction, unless it be expressly desired; and, in this last case, to request an immediate consultation with the practitioner previously employed.

SECTION 10. When a physician who has been engaged to attend a case of midwifery is absent, and another is sent for, if delivery is accomplished during the attendance of the latter, he is entitled to the fee, but should resign the patient to the practitioner first engaged.

The foregoing sections of the code embrace points in ethics and etiquette the propriety and importance of which no member of the medical profession will undertake to deny. Their observance is essential to the harmony, good fellowship, and mutual co-operation of practitioners of medicine, thereby contributing to the honorable character of the profession, to public confidence in regard to it, and to its usefulness in the cause of humanity. The question, however, may be raised, Is it necessary to embody these points in ethics and etiquette in formal rules; that is, would not physicians regulate their conduct equally well without the latter? The affirmative answer to this question would imply that all those admitted to the ranks of the medical profession found "their expectations of practice upon the extent of their qualifications, and not on intrigue or artifice." No one will venture to claim for all members of the profession that purity and high moral tone which are implied in the affirmative answer to the question. It must be admitted that these rules are not infrequently violated. Does it follow that the rules are useless? Certainly not. The fact only proves that knowledge of rules does not always secure their observance. This is true, not alone in medical ethics, but in theology, law, and every department of morals. That prescribed rules of medical ethics influence more or less the

conduct of physicians can not be doubted. This is true as regards other duties, else, wherefore the propriety of such rules applied, not only to the higher moral relations of human life, but to those of minor importance, and even the trivialities of social intercourse. To do away with ethical rules for the reason that they are not always observed would be in opposition to human experience and conducive to anarchy. Prescribed rules of conduct are of use by giving distinctness and force to popular sentiment. Moreover, the knowledge of rules affects the conduct of those who, not devoid of rectitude, pursue the wrong because they do not know the right. Rules thus tend to nullify the temptations and the specious pleadings of apparent self-interest.

It has been argued for the inutility of rules in medical ethics, that penalties for their non-observance are with difficulty instituted and enforced. This argument is as illogical as in its application to all other moral duties. It is a feature of the code of medical ethics that it takes no cognizance of penalties for violations of its requirements. It appeals solely to the judgment and conscience. Measures for the enforcement of its rules are left entirely to the discretion of local associations. These measures admit of discussion and differences of opinion. They may be injudicious in respect of undue laxity on the one hand, and, on the other hand, of over-strictness. In either case, the propriety and the importance of the rules remain unaffected. Whether violations of ethical rules shall be silently passed by, or occasion only personal expostulation, or be met by the tacit disapprobation of professional brethren, and under what circumstances they call for disciplinary measures, together with the forms of discipline called for in particular cases, are questions the consideration of which does not fall within the scope of these commentaries.

Reference has repeatedly been made in the course of these commentaries to the importance of popularizing knowledge of medical ethics and etiquette. This is especially desirable with respect to the "duties of physicians in cases of interference." Recognizing the propriety of the rules laid down in the code, knowledge of them would lead to co-operation on the part of the public in securing their observance. It is a common impression that, intrinsically, the ethical rules have no binding force; that they are restrictive without regard to individual rights and the claims of humanity. The observance of rules of etiquette is regarded as a frivolous formality. Let the rules of ethics and etiquette be understood by those without, as well as by those within, the profession, and deliberate violations of professional duty and propriety will be likely to fail in their objects. Public opinion will concur to render disreputable those who are guilty of unprofessional conduct.

SECTION 9. A wealthy physician should not give advice *gratis* to the affluent; because his doing so is an injury to his professional brethren. The office of a physician can never be supported as an exclusively beneficent one; and it is defrauding, in some degree, the common funds for its support, when fees are dispensed with which might justly be claimed.

For two reasons this section of the code has a limited application. In the first place, the number of wealthy physicians is small; in the second place, most physicians who

are wealthy are as willing to accept fees as they who are in moderate circumstances. The rule was doubtless intended to apply to instances in which a wealthy physician gives out, or has it understood, that his services are free to those who can afford proper remuneration as well as to the poor. The intent could not have been to enjoin it as a duty to receive fees in every instance from the affluent. There are circumstances under which, from delicacy or other motives, physicians are unwilling to be paid for their services, irrespective of the pecuniary ability of the patient. No one has a right to judge of these circumstances but the physician himself. Offenses against the intent of this rule must be extremely rare. As a measure of policy, with a view to obtain and retain practice, it would not be likely to succeed. With some exceptions, patients able to pay for medical services would not consent to continue long to receive them gratuitously. As an illustration, a medical friend of the writer, whose practice was largely among the affluent, kept no regular books, and sent no bills for fifteen years. The explanation which he gave was that he did not need any income from his practice, and he was too indifferent thereto to incur the trouble of making charges and collecting accounts. As a result, the greater part of his patients left him, preferring the services of those whose practice was on a business basis.

Persons who have relinquished medicine for other pursuits, and those who have pursued a partial course of medical study, are sometimes fond of playing the part of a *dilettante* practitioner. Except in cases of emergency, this is an impropriety which does injustice to the medical profession, to say nothing of the risk of injury to patients. An illustration of this risk, at the time of writing these remarks, has fallen under the writer's notice. An English clergyman, who had given some attention to the study of medicine as an amateur, was arrested and committed for trial on the charge of having caused the death of a young girl by administering oil of bitter almonds. There was no evil intent in giving the remedy, but, from ignorance, it was given in a poisonous dose. The counsel of the accused admitted the case to be one of "homicidal misadventure." The London "Lancet" concludes a notice of the case by saying: "We may hope that Rev. Mr. T.'s ample admissions and benevolent career will simplify and shorten a trial which, however, ought to serve as a warning to clergymen to remember that the weapons of their warfare are not medical."

Complaint is often made of the injustice done by dispensaries and clinics on the same ground as that of gratuitous advice to the affluent. The complaint is a valid one, in so far as these institutions furnish gratuitously medical and surgical aid to those who have no right to assume the claims of poverty. It is difficult in the administration of medical charities to escape imposition. To do so, as far as practicable, is plainly a duty, not alone to the medical profession, but to those by whom the charities are maintained, and to those for whose relief they are instituted.

ART. VI.—Of Differences between Physicians.

SECTION 1. Diversity of opinion and opposition of interest may, in the medical as in other professions, sometimes occasion

controversy and even contention. Whenever such cases unfortunately occur, and can not be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians, or a *court-medical*, or, where both parties are members of the medical society of their county, to the censors.

SECTION 2. As peculiar reserve must be maintained by physicians toward the public in regard to professional matters, and as there exist numerous points in medical ethics and etiquette through which the feelings of medical men may be painfully assailed in their intercourse with each other, and which can not be understood or appreciated by general society, neither the subject-matter of such differences nor the adjudication of the arbitrators should be made public, as publicity in a case of this nature may be personally injurious to the individuals concerned, and can hardly fail to bring discredit on the faculty.

"A doctors' quarrel" is an expression often made use of in a way to imply an event of common occurrence. It may be affirmed that doctors are not more given to quarrelling than those engaged in other pursuits. Indeed, the mental influence of their professional duties is in an opposite direction. The occasions, however, of controversy and contention among medical men are apt to be not understood and appreciated by others. This is implied in the often-repeated saying, "Who shall decide when doctors disagree." Hence it is that the controversies and contentions of physicians are regarded as denoting a quarrelsome tendency.

Contentions among physicians for the most part are brought about by gossiping busybodies and go-betweens. Some persons seem to think that they can not compliment a physician more highly than by disparaging his competitors. Certain of his friends are not content with the ordinary manifestations of friendship, but they feel it incumbent upon them to depreciate as much as possible the merits of others. His partisans seek to draw from him expressions derogatory to the character or practice of the practitioners to whom they are opposed. His words are misinterpreted, and his silence may be misconstrued. Tale-bearers are ready to carry offensive reports to those to whom they refer. Resentment and retorts naturally follow. Thus it is that they who should be brethren are at sword-points. Now, generally this result might be prevented by a very simple procedure. Let any one who is led to impute a grievance to another practitioner at once seek an explanation in a spirit of kindness and charity. The result will be, in nine cases out of ten, that either the imputation is without foundation, or a satisfactory apology will be obtained. Such an explanation may tend to produce mutual confidence and cement friendships.

Harmony among physicians is most desirable, not alone for the comfort of those concerned, but as conducive to the honor and usefulness of the medical profession. It is essential to co-operation in medical consultations, in measures for public health, etc. For the maintenance of harmonious relations, local associations are important. In places of small or moderate size, these associations should embrace all the members of the profession of the community who are in good standing. In this way are avoided the evils of cliques, which are to be deprecated. The local associations should have more or less of a social character. They afford oppor-

tunities for intimate acquaintance, for the explanation of misunderstandings and for their prompt adjustment. Observation will show that, in the places in which such associations exist, much more harmony and good fellowship prevail than in the places in which physicians are not brought together in social intercourse. Controversies and contentions, however, can not always be avoided. They will be terminated with the more difficulty the longer they continue. The code of ethics, therefore, judiciously instructs that, if not terminated *immediately*, they are to be adjusted by arbitration. The method to be preferred is for the parties to select disinterested and unprejudiced persons as arbitrators, having previously agreed to abide by their decisions. In this way publicity may be avoided. But, if a supposed grievance involve a question of flagrant unprofessional conduct, there may be no alternative beyond a formal complaint to and an adjudication by an organized society, embracing among its powers regulations for investigation and discipline in such cases. The code instructs that the *censors* of a county society are to adjudicate. This, evidently, should be left to the action of the society, which may refer these matters to a special committee on ethics, or to committees appointed for the purpose in particular cases. Here, as elsewhere, the code takes no cognizance of the modes of discipline. Each society may determine these without regard to the action of other societies. The reasons for secrecy as regards the subject-matter of the adjudication of differences among physicians are succinctly but amply set forth in the code. Secrecy, however, can hardly be expected when expulsion from societies and exclusion from professional fellowship are the penalties inflicted. Nor, with a view to a salutary moral effect, would secrecy, under these circumstances, be desirable, were it practicable.

ART. VII.—Of Pecuniary Acknowledgments.

Some general rules should be adopted by the faculty, in every town or district, relative to *pecuniary acknowledgments* from their patients; and it should be deemed a point of honor to adhere to these rules with as much uniformity as varying circumstances will admit.

By no process of distortion can this article of the code be made to inculcate a combination, after the manner of trades-unions, to establish and enforce a certain rate of wages for medical services. The article applies fully as much to exorbitant as to inadequate pecuniary acknowledgments. It is plainly important, for the convenience of patients, as well as of physicians, that in every community there should be an understanding as to the customary fees for the different kinds of service which medical men are expected to render. It would be extremely incongruous in ordinary practice for the physician, before giving advice or making a professional visit, to state the amount of compensation which he will require, although, in certain cases, to do so is not only proper but advisable; nor, as a rule, should patients be expected, whenever a physician is summoned, to inquire respecting his fee, albeit, under certain circumstances, this is both decorous and desirable. Exclusive of exceptional instances, which will be presently referred to, the adoption of some general rules, and their recognition

within and without the profession, obviate the necessity of questions, explanations, and discussions, which are often embarrassing and disagreeable.

The poor policy of under-bidding other physicians, for the sake of gaining practice, would probably deter those from pursuing it who might be so inclined. The adage, "dear at any price," would be applicable to physicians relying on this policy. This is well understood by the public. Few patients are disposed to select a medical adviser because he places a low pecuniary valuation on his services. Necessity alone would dictate a choice on this ground; and it is rarely the case that inability to pay the customary fees prevents patients from having the services of those whom they prefer. The code by no means interdicts deviations from the general rules according to varying circumstances. It is to the honor of the profession that the instances are few in which efforts for the relief of suffering and the preservation of life are withheld on account of inability to make an adequate pecuniary acknowledgment. The circumstances which lead physicians from sympathy to deviate from the general rules are often not apparent to others. Few persons outside of the medical profession are aware of the extent to which the services of its members are freely rendered, with but little or no compensation; hence, one reason for an exaggerated estimate of the incomes of those largely engaged in practice, and for the fact that the majority of practitioners, after a long professional career, leave but little property. The physician, from his intimate relations with his patients, comes to know often their limited resources, of which, perhaps, others are ignorant; how can he add to their embarrassment and anxiety by exacting full payment for his services? A considerable proportion of those to whom these services are gratuitously rendered do not come to him *in forma pauperis*, but silently appeal to his benevolence. While it can not be assumed as a principle that the remuneration received from the affluent should be sufficient to compensate for services to those unable to make pecuniary acknowledgments, the fact that these services are rendered in the cause of humanity should be considered as a reason for the ready and cheerful payment of fees by patients who have no claims on the charity of the profession.

A demand for exorbitant fees is not in accordance with this article of the code. When based on an assumption of extraordinary knowledge or skill, it is an imposition, and it is, of course, fraudulent if services have been falsified. An exorbitant fee can not be claimed on the score of the wealth of a patient. Such a patient may add to the fee an *honorarium* which, considering the services rendered by a physician to those unable to make pecuniary acknowledgments, may be accepted without compromising self-respect. Extraordinary services rightfully claim deviations from the general rules in respect of fees. Detentions or constant attendance, involving sacrifice of interests, unusual fatigue, or impairment of comfort, and visits requiring traveling and absence from home, are in this category. No one but the physician himself can place a valuation on such services, and it is his right to do this, provided there be an understanding before the services are rendered. If the expense

of certain services be stated beforehand, patients or their friends can have no occasion for complaint, and thereby the risk of unpleasant feelings, and, it may be, a suit at law, will be avoided.

Inasmuch as it is the custom in this country, after medical services have been rendered, either for the patient to request to know the amount of indebtedness, or, if not requested, for a bill to be presented, it is unbecoming to leave the amount of pecuniary compensation to be determined by the party who has received the services. It is to be assumed that the services have a certain valuation, varying, of course, according to circumstances in particular cases. To decline to fix on any valuation, provided patients be affluent, is virtually to appeal to their generosity, and this is certainly undignified. If the valuation by patients be higher than that of the physician, the difference is easily made up by an honorarium. The exceptions to the rule that the physician should determine the value of his services are in some instances in which the pecuniary resources of the patients are either unknown or known to be limited. For a physician to keep no account of medical services, relying on the voluntary contributions of his patients for his support, is not only unseemly, but derogatory to the profession. Medical as well as other services are entitled to compensation, whenever they are not charitably bestowed, and it is disreputable to place pecuniary acknowledgments in the light of a gratuity.

THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.

By HENRY G. PIFFARD, M. D.

First Article.

COMPARATIVELY few are acquainted with the history of the events that led to the movement which resulted in the formulation of the New Code of Ethics of the Medical Society of the State of New York. The writer of this considers himself fairly well informed on the subject, and will give what appears to him the facts pertaining to the subject. In doing this, however, he must be pardoned for certain apparent digressions, since, in order that the matter may be correctly understood, it will be necessary to go back to the times that precede the promulgation of the "Old Code."

Prior to the year 1845 the medical profession found itself in the presence of certain evils and inconveniences that appeared to the leaders of professional sentiment to be adverse to the interests and welfare of the medical profession. This was specially felt in the State of New York, and it was in this State that the matter was first seriously considered.

In New York the profession first became organized as a corporate body in the year 1806, and seventeen years later thought fit to lay down a set of rules for the government of its members. This action was deemed necessary in order to control some who appeared to regard medicine in the light of a trade rather than a profession, and who were regarded by their stricter brethren as medical freebooters rather than physicians. The result was the enactment in

1823 of the "System of Ethics of the Medical Society of the State of New York." This "system" or code inculcated two species of obligation, namely: those which the profession should bear to the public, and those which its individual members should hold to each other. This code was founded on and was an adaptation to local needs of an English work known as "Percival's Ethics." At this time there was little cause for uneasiness on the part of those who with propriety might be called "regular physicians," namely: those who were graduates of medical schools, and those who, after strict examination, were "licensed" to practice the profession by the bodies having due authority thus to license—to wit, the county societies. During these years, however, an irregular sect had come up, outside the profession, and who were commonly spoken of as the "steam-doctors" and "herb-doctors." These were men of no medical acquirements, and of varying degrees of honesty, who had embraced the doctrines of one Samuel Thomson, hailing from New England. Their chief therapeutic reliance was on vigorous sweats with the free use of lobelia and the utter condemnation of mineral and certain other powerful drugs. The clamor that they raised against the heroic treatment then practiced by the mass of the profession resulted in a most bitter feud, in which the laity, as is usually the case, took an active interest. The State government was appealed to, and for nearly twenty years the strife was kept up, sometimes the profession and sometimes the quacks being ahead. In 1827, however, the profession gained a definite and substantial victory, the medical act of that year placing in their hands the supreme control and regulation of the practice of medicine in this State. At this time the State society had less power over the county societies than at present, and the suppression of quackery was virtually left in the hands of the county societies, each having jurisdiction in its own district. The war against the irregulars, just mentioned, was kept up with more or less vigor in different localities. During the fourth decade of this century, however, a new form of irregularity appeared. I refer to the introduction of Hahnemannism or Homeopathy; terms which in those days were synonymous. This new form of heresy developed, not among the irregulars, but in the bosom of the profession itself. The adherents and advocates of the new doctrines were members in good standing of the county societies, and their brethren were unable to invoke the aid of the law to compel them to practice in accordance with the views and wishes of the majority. Another weapon, however, was brought into play, namely: social and professional ostracism. The public, as before, became interested in the quarrel. Many of the laity regarded the action of the majority as a species of oppression, and, as often happens, became partisans of the weaker party. During this decade the number of professed homœopaths increased and their adherents and supporters multiplied. The heretics were still members of the county societies, and there was no easy way of ridding the societies of them—that is, against their will. At that time the only way in which a member could be expelled from a society, and prevented from continuing his practice, was through a direct application to the courts. The courts, however, were

unable or unwilling to give the societies the desired relief, feeling, perhaps, that they had no more right to interfere in matters of professional than of religious heresy. The societies, nevertheless, possessed one valuable franchise: They could prevent any new comer from practicing in their respective districts if they saw fit to do so. This afforded them the means, as they thought, of preventing the increase of homœopathy by accessions from abroad. About the year 1842 the Orange County society, I believe, availed itself of this power; and forbade a physician of homœopathic tendencies from practicing in that county. Fearing that he would in like manner be prevented from practicing in the other counties of the State, he gathered his friends together and, without much difficulty, procured the passage in 1844 of a law that deprived the county societies of their powers in this respect. This law, moreover, went much further than this, as it repealed the penal clause of the act of 1827 and virtually permitted any who chose, whether educated or not, to practice medicine in this State. This permitted quacks of all sorts and descriptions to ply their vocation without fear of molestation. This condition of affairs was maintained for thirty years, and there can be little doubt that this was the direct result of the injudicious action of the Orange County society, indorsed as it was by the then general sentiment of the profession throughout the State. Homœopathy now had free scope to extend its influence, and, as the evils of sectarian medicine were most keenly felt in New York and Pennsylvania, these States were among the foremost to consider how they might be averted. The result of this consideration was the birth of the American Medical Association. It seemed probable to this association that the most effective blow would be given to the new-born heresy, if the profession as a whole combined against it. It seemed necessary that the homœopaths as a body should be absolutely excommunicated from professional recognition and intercourse, and that the public at large should know it. In the code of ethics, and especially in the "consultation" clause, this sentiment crystallized. It was thought that the public, knowing that consultations were forbidden, would be afraid to intrust serious cases to the care of a homœopath who might be scores of miles distant from a colleague with whom he might consult. This action was, to say the least, exceedingly unwise as judged from a purely medico-political standpoint. In those days the chief therapeutic reliances of the profession were bleeding, purging, puking, blisters, and salivation. In contrast to this the homœopath offered medication that was not unpleasant to take, nor, apparently, disturbing in its effects. Is it a wonder, then, that many persons, finding themselves but trivially affected and yet desiring professional advice, preferred the milder to the severer medication? Happily recovering, they felt emboldened to trust even severer cases to the homœopath. The general profession, however, were blind to the teachings of these everyday occurrences, and it was not until Andral, in France, demonstrated in the hospitals of Paris that no treatment was preferable in certain diseases to the methods in vogue, that medical men awakened to the fact that in many cases they were doing their patients harm rather than good.

In England, Sir John Forbes learned the lesson, and endeavored to teach it to his countrymen. The reward he reaped was the scorn and hatred of his peers, and, after his death, the virtual adoption of his views (expectant treatment) by a succeeding generation. He simply taught that entire absence of treatment was often better than the heroic methods practiced by his colleagues. During these years the homœopaths, despite the opposition of the profession, increased in numbers and in influence, and, excluded by the "code" from joining the existing medical corporations, they applied to the State for authority to form corporations of their own. This they secured, with powers co-extensive and identical with those possessed by the older societies. Most of the older homœopaths joined the new organizations, but there was still left a certain leaven of unrighteousness, which the majority desired to get rid of. This could hardly be accomplished under existing laws, as the societies had not the power to prune their membership, except through an application to the courts. This was felt to be an inconvenience, and the Legislature was applied to for relief. Through the exertion of Dr. J. G. Adams and others, a law was enacted, in 1866, which greatly enlarged the powers of the county societies in this respect. The law in question permitted them to frame by-laws (subject to the supervision of the State society) which would enable them to visit expulsion on any member who should be guilty of irregular practices. The term "irregular practices" was a little indefinite, but was commonly understood to include employing remedies or methods that in any way resembled or savored of homœopathy. In the year following the passage of the act, the Westchester Medical Society invoked its aid to enable them to get rid of an obnoxious member who was charged with "irregular practice of medicine." Apparently the gravest charge against the member was the admitted fact "that he has purchased globules of sugar of milk by the pound from the Homœopathic Pharmacy in New York City," and "that he used these homœopathic globules in his practice, to induce his children patients to take the medicine which he prescribed for them." On these charges he was expelled by the county society, and, on the member's appeal to the State society, the action of the county society was sustained. The expelled member, if he desired professional affiliation, was now forced to join the homœopathic society. In this way the ranks of that body obtained occasional recruits. I do not mean that there were many formal prosecutions for the crime of giving the children a little candy, but the social and professional pressure was so great that many left the regular societies voluntarily, in order that they might obtain a little peace from persecution and be enabled to practice as they thought best. It is a curious fact that, while the regular societies *excluded* the use of certain medicines and modes of employing them, the homœopathic societies were really more liberal in this respect, none of them, I believe, having formally adopted the exclusive tenets of Hahnemann, or declared that their members must practice exclusively in accordance with the doctrine of similars. So far as I am aware, they never expelled any of their members who found that "confectionery" ("Zuckerkauen," as the decision of

a German court of justice recently termed it) was not always sufficient, and who supplemented it with a good dose of quinine or calomel. The homœopaths, then, were, practically at least, less exclusive than their elder brethren. Many physicians, who, led by a spirit of inquiry, investigated the homœopathic system, found some apparently striking verifications of the doctrine of similars, forthwith fancied that in these consisted the whole science and art of medicine, and made use of them as occasion required. This led to their ethical condemnation, and forced them into the established homœopathic organizations, in some instances long before they had any settled convictions on the subject. There is little doubt that the general effect of the "code" was, in many ways, to build up and strengthen the sectarian societies, not only by forcing men into them, but by exciting public sympathy in their favor, and thus aiding them politically. A house divided against itself can not stand, and a medical profession divided into hostile camps can not long retain the respect of the public, nor the good-will and assistance of the legislators.

Going back some years, we witness the birth of still another medico-political organization. The old herb- and steam-doctors, some of whom had picked up a smattering of medical knowledge, began to form voluntary organizations for mutual protection. Before long they, too, aspired to corporate powers and governmental recognition. The existing feud in the profession rendered this a comparatively easy matter. Under the title of "Eclectics" they secured the same chartered rights as the other societies. There is little doubt that at this time the homœopaths aided the eclectics, believing that, by forming an alliance with them, they could prevent the regulars from in any way curtailing the corporate powers of either body. For obvious reasons an alliance of this sort could not be very long maintained. The homœopaths, as a rule, were educated men, while the vast majority of the eclectics were not. There was, however, another cause that tended to isolate the eclectics from the educated profession, and this was their code of ethics. Following the example of the regulars, the homœopaths adopted a code that was a verbatim copy of the American code, with the single exception of the consultation clause. The eclectics, however, adopted a code which in every important respect was the exact reverse of the American code. In their code they stated that it was proper for medical men to hold patents on surgical instruments, to advertise in the papers, to invite laymen to operations, to practice with secret nostrums, etc. Such practices most medical men regard as eminently improper, but this did not alter the fact that these men were in the eye of the law fully as regular as the very elect. This position they never would have obtained had it not been for the existing feud between the regulars and the homœopaths.

We now had in the State of New York three medico-political bodies, each with co-ordinate powers and co-ordinate jurisdiction. The differences between them were essentially as follows: The first or older organization and the second one were at variance simply on the question of practical therapeutics, while on questions of general medical polity they thought alike. The third organization differed

from the others, both on the question of therapeutics and medical polity. One might suppose that the State of New York was by this time sufficiently afflicted, but such was not the case. A few years later, still another body, claiming to possess certain special therapeutic advantages, obtained corporate privileges and governmental recognition. But this was not all; the repeal of the penal clause of the act of 1827 permitted quacks and charlatans of every kind to come to the State and deceive the unwary in any manner that they chose. Such was the condition of affairs up to 1874. At this time some one—I have never been able to ascertain who—introduced into the Legislature a bill to regulate the practice of medicine in this State. This bill would appear on its surface to have been a desirable measure, but a careful study of it ought, at the time, to have revealed its true inwardness. If this bill was not originally drawn by the eclectics, it was unquestionably manipulated by them during its passage through the Legislature, and practically it turned over to them the licensing of every quack in the State who thought it worth while to pay them an examination fee of ten dollars. The majority of them, however, did not take even this trouble. They had enjoyed immunity for thirty years, and were not afraid to take the risks a little longer. As a matter of fact, the few prosecutions that were undertaken came to a lame and impotent conclusion.

This, then, was the state of medical affairs in New York about the year 1876. There were, first, the regular profession, enjoying chartered rights that dated back for seventy years, and consisting of men who were graduates in medicine, or licentiates (after examination) of the county societies; second, a sectarian offshoot from them, who were likewise educated men; third, a sect growing up by itself, and slipping into corporate existence while the first and second were quarreling—an exceedingly small number of these men had received a medical education; fourth, a sect that died almost at its birth; and, fifth, the horde of miscellaneous quacks who settled in the State during the times when this could be done with impunity. All of these things were brought about during the period that the profession were under the guidance of the code of ethics of the American Medical Association. Surely, if the object of this code were the suppression of quackery, its success can hardly be described as brilliant. How it is in other States, the profession there resident are the best judges. In what precedes and follows, I am speaking only concerning the State of New York. With quackery rampant to a degree never before witnessed in this locality, the problem to be solved was, What were the causes and what was the remedy? These questions could certainly not be answered off-hand and without consideration. The problem was one that required careful and earnest study, if a correct solution was to be reached. This study was undertaken by the then officers and censors of the Medical Society of the County of New York, whom the law had constituted the guardians and protectors of professional honor and professional interests within their jurisdiction. Almost the first conclusion at which this body arrived was, that the laws regulating the practice of medicine were palpably defective. With prac-

tically no law from 1844 to 1874, and after that a worse than no law, it was clear that, until an efficient statute was enacted, it would be impossible to expect much, if any, improvement in the affairs of the profession. At this juncture a gentleman who had acted as the legal adviser of the society offered to prepare a suitable bill, and endeavor to procure its enactment. His offer was accepted. A bill was prepared, and introduced in the Senate. This bill was referred to a committee, and an hour was assigned for its consideration. At the appointed time the advocates and opponents of the bill presented their views to the committee, which was represented solely by its chairman, Dr. Ray V. Pierce, of Buffalo, a noted medical advertiser, and a member, we believe, of the eclectic organization. The bill did not meet the approbation of the committee, was not reported favorably to the Senate, and did not become a law. The next attempt to secure suitable medical legislation was made by the State Medical Society. In 1880 it instructed its Committee on Legislation to prepare a proper law and submit it to the Legislature. This was done, and the Medical Act of 1880 was the result. Prior to the passage of this act there were in the State upward of one hundred and fifty bodies that were competent to legitimize practitioners of medicine. The act in question reduced the number to thirteen. Of these bodies, two were eclectic, two were homœopathic, one was nondescript, and the rest pertained to the regular school. Within the past year two of these bodies have been declared illegally constituted, and their career has ended. In 1882 an attempt was made by the State society to reduce the number of licensing bodies to one. The bill which was drawn for the purpose of effecting this object did not become a law. The law of 1880 remains in force, and under it the entire responsibility in regard to the licensing and legalizing of practitioners in the State rests with the medical colleges of the State, while prosecutions for violation of the law may be undertaken either by individuals or the county societies. In New York County these prosecutions have been numerous, and usually successful. Thus far but one flaw or serious imperfection in the law has been discovered—namely, that the penalty for perjury in connection with registration is not sufficiently severe. Shortly after its adoption, our Pennsylvania brethren procured the enactment in that State of a law identical in its main features with the New York law. That the New York law is all that is to be desired, or that it is the best medical act in this country, is far from being claimed. In fact, I believe that Illinois and North Carolina have better ones, both from a theoretical and practical standpoint.

From this *résumé* of the medico-political situation it will be seen that, after a sharp fight with quackery, the profession obtained the upper hand in 1827; that for several years it retained this control; that in 1844 it lost its power, and failed to regain any of it until 1880; that even now it does not possess the full powers and privileges that it formerly enjoyed.

I shall next consider the medico-educational and the medico-ethical status of the State, and afterward endeavor to read the lesson of the past, and point out the path that

the profession should follow if it hopes or desires to regain its lost power, and to occupy the vanguard in medical affairs in this country.

(To be continued.)

REMARKS ON THE GENERAL ARCHITECTURE OF THE NERVOUS SYSTEM OF MAN.

By AMBROSE L. RANNEY, M. D.,

ADJUNCT PROFESSOR OF ANATOMY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

This article, together with some others that I purpose to contribute to the "New York Medical Journal" shortly, formed the introductory lecture of my course during the winter. The other articles alluded to made up the continuation of the course. This fact will explain the elementary character of much that is here stated.

In man and the vertebrates the cerebro-spinal axis may be divided into three separate portions—each perfectly independent of one another, and yet very intimately connected. These are as follows:

1. THE CEREBRUM.
2. THE CEREBELLUM, AND THE APPARATUS OF CEREBELLAR INNervation CONNECTED WITH IT.
3. THE MEDULLARY PORTION OF THE SPINAL CORD, AND ITS EXPANSIONS TO THE DIFFERENT PARTS OF THE ENCEPHALON.

The nervous system of all animals may be subdivided into two distinct histological elements, *nerve-cells* and *nerve-fibers*. The former may be compared to the battery-cells of an electric circuit, the latter to the wires which conduct the current generated in the batteries. The nerve-cells are the chief histological elements of the so-called "gray matter" of the brain and spinal cord, and of ganglia found in other parts; while the white substance of the cerebro-spinal axis may be subdivided by the microscope into distinct fibers, which serve to connect the nerve-cells of some particular region with other nerve-cells or with the muscular apparatus. Nervous impulses may be divided into two classes: centripetal or *sensory*, and centrifugal or *motor*. The former travel from the peripheral portions of the body toward the nerve-centers, while the latter cause the muscular apparatus of the body to act, either in direct response to a sensory impression received from without (reflex movements), or as the result of volition. Microscopical research enables us to state positively that both of these two forms of nervous impulses are conducted partly through direct tracts of nerve-fibers, and partly by the intercommunication established between nerve-fibers and nerve-cells, and nerve-cells with each other. We may infer, therefore, that nerve-cells as well as nerve-fibers serve to maintain *isolated conduction* of nerve impulses; and that the former also generate and in some instances record them (cells of memory). We find the morphological expression of the first statement in the fact that the nerve-cells lie with their long axis stretched in the direction of the fibers with which they are connected, while the second and third propositions are established by physiological research respecting the functions of different regions of the cerebral cortex, as well as by the

named, from their contiguity to this plane, the "*basal ganglia*." Each anterior mass is called the "*corpus striatum*," from the striated appearance of a section made through its

FIG. 3.—DIAGRAM OF THE COMMISSURAL FIBERS OF THE ANTERIOR REGION OF THE BRAIN. (After Luys*.)

These form a series of curves one within another, the extremities of each of which plunge into the homologous regions of each cerebral lobe, 1, 1', 2, 2',—3 and 3'. They pass through the middle line, and at 4 and 4' give rise to the various appearances which the corpus callosum presents. 5, Commissural fibers of the inferior regions. These are curved in an inverse direction as regards the former, the convexity of each set being presented toward that of the other.

substance; * the posterior mass is called the "*optic thalamus*," from a supposed association with vision attributed to it by early investigators.

3. The *cerebellum* presents collections of gray matter which occur partly in layers (*cerebellar cortex*) and partly as scattered masses within its substance.

4. Finally, the so-called "*tubular gray matter*" (which may be traced as a lining to the inner portions of the cerebro-spinal axis from the tuber cinereum to the conus medullaris of the spinal cord) must be recognized as the permanent expression of the primitive and generic type of brain.

The diagram shown in Fig. 2 will make these subdivisions of the gray matter of the cerebrum, as well as the fibers which connect them, more apparent than a long verbal description. It will be seen that the gray matter of the cortex is arranged like a cap to the brain, and embraces the "*basal ganglia*," the "*claustrum*," and "*corpora quadrigemina*"—intermediate portions being left which in the brain itself appear as a white, cheesy mass. These are filled in with lines indicating the different sets of nerve-fibers, as the microscope in the hands of late observers has shown them to exist, and of which this so-called "*white substance*" of the brain is chiefly composed. [A careful study of the text accompanying Fig. 2 will enable the reader to grasp the general direction and terminations of the sets of fibers described.]

It will be seen that certain fibers spring from the cortex, and, after taking a direction which tends to bring them to the level of the superior point of union of the two cerebral hemispheres, cross over to the side opposite to that from which they arise. After crossing, they can be traced to *homologous regions* of the cortex of the opposite

hemisphere. These are called "*commissural fibers*." They are supposed to be the connecting wires between corresponding portions of the cortex of the cerebral lobes, by the aid of which the right and left hemispheres can act in unison with each other when circumstances chance to demand it. These fibers have a direction which corresponds as a rule to the form of the letter U, and they constitute the transverse fibers of the *corpus callosum*—the connecting band of white matter between the hemispheres, seen at the bottom of the median fissure of the cerebrum when the lobes are separated. Commissural fibers can be traced also between the hemispheres (in certain sections of the brain) as an inferior band which lies below the level of the basal ganglia (Luys). There is reason to believe that these connecting fibers (which form nearly if not quite one half of the white substance of the cerebrum) are sufficient, in point of number, to allow of an anastomosis of the gray matter of the cortex of the two cerebral lobes, cell to cell. In infinite numbers they seem to spring from every region of the cortex—either directly from the protoplasmic structure of the cell elements, or as delicate fibrils which can be traced no farther than the intercellular structure, where their delicate sheaths become lost.

(To be concluded.)

Correspondence.

LETTER FROM BOSTON.

Boston, April 1, 1883.

THE approaching dedication of the new building erected for Harvard Medical School renders quite apropos a little gossip regarding the school and its needs, as well as a concise description of the magnificent quarters on the Back Bay into which this important department of Harvard University will soon move. Let it be premised, first, that Harvard Medical School, in the words of one of its most distinguished sons, "has for ever been outgrowing itself." When it entered on its grand mission it was crowded into the old Holden Chapel at Cambridge, with a staff of three teachers. In 1810 and 1816 changes in location were made, the first to number 49 Marlboro' (now Washington) Street, and the second to a small building in Mason Street. It was in 1846 that the next removal was made, this time to the North Grove Street building. Here, for some years, at least, there was room enough; but the rapid increase in the number of students (now more than two hundred and seventy-five) brought an attendant call for enlarged facilities in all departments. This demand, of course, has been a yearly increasing one. The laboratories have been among the makeshifts of the old North Grove Street building, while the insufficient lecture-rooms have long been unfit for the uses to which they have been subjected. The Museum of Pathological Anatomy, too—that precious accumulation of a century which the school cherishes so proudly—has been a mere tinder-box, the valuable collections of models, casts, specimens, books, and apparatus having been afforded no protection from fire. It was at this point in the career of the medical school that, after one hundred years of

* This ganglion has two parts (as shown in Fig. 2)—the *caudate nucleus*, and *lenticular nucleus*.

work for humanity, an appeal went forth to its friends. The response was prompt and highly encouraging. More than \$250,000 was given that a building might be erected which, in size and interior arrangements, should serve as a fitting structure in which to carry on the work so well begun. With very slight delay, a site was soon selected, offering really splendid advantages, from its proximity to our great Public Library, the Art Museum, and the rooms of the Massachusetts Natural History Society. It is, too, equidistant from the Massachusetts General and City Hospitals and Boston Dispensary, and shadows the walls of the new Children's Hospital. This site is a portion of what our city government has recently and appropriately named Copley Square, and is in a section of the city unequalled for the beauty of its architectural development, as well as possessing the added advantage of convenient situation. A sufficient quantity of land having been purchased (an eye to the demands of a more remote future was had in this respect, by the way), the faculty stated their requirements to the corporation of Harvard University, and soon, thanks to the efforts of a large committee of the medical teachers, the architects' plans were submitted and approved, and the workman's hammer was shortly heard binding the bargain.

The building now so near completion occupies a lot of land, 264 × 125 feet, on the corner of Boylston and Exeter Streets, having a frontage of 123 feet on Boylston Street, 100 feet on Exeter Street, and 131 feet on the back lane. It stands back 15 feet from the latter street and 25 feet from the former. The remainder of the lot forms a yard, 125 × 100 feet, inclosed by high brick walls, entered from the back lane and containing horse sheds and similar conveniences, besides a rear entrance to the building proper. The new school is entirely in the Renaissance style of architecture, freely treated, and developed in brick, with moldings, etc., of red sandstone and with decorative panels of terra cotta. It has four lofty stories and a flat roof, surrounded by a skyline of stone balustrades and low gables, the latter marking structural divisions of the interior. The height of the building from the sidewalk to the top of the balustrade is 77 feet. The main front on Boylston Street has three pavilions, the central one of which is slightly recessed. These pavilions are *façades* of the two main divisions of the plans which are formed by the crosswalls running north and south, inclosing in the center a great staircase, 41 × 35 feet, lighted mainly from the roof. The remainder of this central division to the north and south is occupied in all the stories by smaller rooms, serving as offices to the greater halls which occupy the main east and west divisions of the plan. The smaller rooms are mezzanines (half-stories), so that, while the east and west pavilions are four stories high, the central pavilion has six stories. The principal entrance to the building is in the center of the Boylston Street *façade*, by an architectural portico and steps, opening into a great waiting hall 41 × 56 feet, divided into two parts by an arcade of five arches, supported by polished granite columns. Of these two parts, one is the entrance hall and the other, at the rear, the staircase hall. Both are paved with marble, with molded dados and cornices of fine brickwork and plaster wall panels between, decorated with oil paintings. This treatment, by the way, is extended through the six stories of the staircase. The stairs themselves are of iron, with an enriched balustrade of iron, supported by iron columns with decorated capitals; the staircase galleries are eight feet wide, and arranged for tiling on flat floor-arches of concrete blocks.

The structure is throughout as near fire-proof as possible, all the walls being of brick without furrings, with minor partitions of concrete blocks. The floors and roof are of "mete construction," and made of three-inch planks, laid flatwise upon heavy, square beams. On the lower side these beams are

entirely incased with plaster on wire lathings, and embellished with stucco moldings and cornices, to serve as a protective envelope in case of fire. In order to avoid columns, the larger rooms are crossed by compound trusses of iron, also incased in plaster, and into these are framed the wooden floor-beams.

The various rooms and departments of the college are disposed as follows: On the first floor, connected by a wide brick archway with the entrance hall, are the janitor's apartments, occupying the northeast corner of the building, so placed that he may command a view of the exits and entrances, both front and rear, and be in ready communication with all those parts of the building requiring his personal services. On the southeast corner is a large reading- or study-room, 43 × 46 feet, with smoking- and coat-rooms adjoining, all, of course, for the students' uses. The western side of this story is occupied by the faculty-room, library-room, and a lecture- or recitation-room, each apartment being roomy and well adapted to its special purpose. In the second story, over these rooms, is the extensive laboratory for general chemistry, 95 × 36 feet, and 21 feet high, so fitted up that 212 students may work together at the same time. The mezzanines connected with this important apartment are subdivided for special laboratory services and studies, for store-rooms, professors' studies, etc. A portion of these half-stories are also used in connection with the physiological laboratory (36 × 48 feet, and 21 feet high), occupying the northeast corner of this story, and furnished with benches, steam baths, chemical hoods, and all other appliances essential to this division of the school, including, also, private laboratories for the professor and his assistants, and direct communication with the floor of the general lecture-room, which occupies the southeast corner of this story. This hall (43 × 46 feet) is arranged with sloping ranges of seats for 234 students, and the floor is furnished with an experimental table and hoods, with arrangements for illustrative charts and blackboards. The students' access to the lecture-room is from the half-story above, and the space under the sloping seats is utilized by the physiological professor for experimental purposes, storage, etc.

The third full story is occupied in front by the Museum of Pathological Anatomy, 80 feet long by 34 feet wide in one part, and 48 in another, with galleries all around and glazed cases dividing the alcoves. This, by the way, is the famous museum of which Harvard is so proud, and is the finest collective exhibit of its kind in this country. It is to be handsomely decorated with portraits, busts, etc. From the museum there is direct access to the arena of the anatomical theatre in the southeast corner, over the general lecture-room, occupying the height of two full stories, with steep sloping seats for the accommodation of 268 students, who thus, as it were, overhang the table of the demonstrator in anatomy. The students' access to these seats is by galleries opening on the upper corridor of the staircase. Thus they never necessarily come in contact with the instructors and their appliances on the floor. The space under the seats is occupied by the curator of the museum for the preparation of specimens and for storage, and also by the professor of anatomy for his study. The western third of this story is devoted to subordinate lecture- and recitation-rooms. The upper story contains, in the northeast corner, the pathological laboratory, an ample room, excellently lighted from above and on the sides, and furnished with continuous tables provided for microscopical studies. Attached to this room are also other and smaller apartments for special investigation and experiments in connection with the pathological department. The western side of this upper story is furnished with a laboratory for anatomical study, and has 14 tables lighted by a continuous arcade on the side and by numerous skylights. At the southern end of this laboratory is a smaller theatre for anatomical demonstra-

tion, capable of accommodating 80 students; and connected with it, on the south side of the story, are smaller rooms for preparation and storage. These smaller rooms on the south side in all the stories are connected by an iron service staircase, with an ample freight and passenger elevator from the basement. The staircase also is continued to the roof, which, besides being flat, is also conveniently designed for certain out-door experiments. The two main transverse partition walls of brick are filled with plastered flues of various dimensions, connected with heating chambers in the basement, and so arranged with valves that the occupant of each room may easily adjust its temperature and ventilation. These flues, after they have served as heating flues, become exhaust flues, and are continued upward above the roof, being furnished in their upper part with inducing coils. They are also used for the escape of chemical fumes from the hoods in the various laboratories. In the middle of each of these transverse walls is a large shaft furnished with inducing coils, and communicating with those apartments where a special service of exhaust is needed. These inducing coils everywhere are connected with a supplementary boiler in the basement, to be used for ventilating purposes only. There are, besides, two large boilers for heating, and a hot-water boiler connecting with an abundant hot-water service throughout the building. The basement has, also, extensive laboratories and various cold rooms, needed for experimental purposes, etc., and fresh-air passages of ample area, connecting with the hot-air chambers which extend along the base of the two main transverse walls. The laboratories are to have bare brick walls, but the lecture-halls, library, faculty-room, museum, etc., are to be furnished with plastered walls, and with pilasters and beams as suggested by the construction, so that each may possess a certain architectural character directly derived from the conditions of structure.

In concluding this description of the building, it may be of interest to many readers to know that the decorative panels of terra cotta—of which there are ten—referred to in the first part of this letter, are placed directly over the entrance portico. These panels are in two rows, of five each, the upper line bearing the following names: Paré, Galen, Hippocrates, Celsus, and Vesalius; the lower, Haller, Harvey, Sydenham, Hunter, and Richat.

With this building, so well adapted to its great purpose, Harvard Medical School enters its second century of existence. It yet has pressing needs in the future, and, of these, endowments are the most urgent. No deserving student should be prevented from entering or compelled to withdraw before receiving his degree, by reason of too high tuition fees. These fees, however, it is apparent, can only be made lower by the endowment of professorships, the establishment of scholarships, and the creation of a large permanent fund, whose income shall be devoted to the current expenses of the school. To this end, sums yielding an income of from \$2,000 to \$4,000 for professorships are desired. The lesser amounts are, of course, attached to clinical professorships, while the more liberal endowments are desired for the scientific professorships. Scholarships for deserving and needy students should yield from \$200 to \$400 annually. At present there are but six offered in this school, four of which (\$200 each) were established by the faculty, and two (\$300 and \$200, respectively) by the will of the late Dr. Barringer, of Scherectady, N. Y. The establishment of a permanent fund—one of the most useful means of promoting the practical work of any school of this description—is also a consummation devoutly to be hoped for by Harvard's friends, a legion of whom are confident that time will witness the realization of their wishes. Then, with the new building and its added advantages, Harvard Medical School may well be considered foremost in its class.

F.

Book Notices.

The Systematic Treatment of Nerve Prostration and Hysteria.

By W. S. PLAYFAIR, M. D., F. R. C. P., Professor of Obstetric Medicine in King's College, etc. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 17 to 111, inclusive.

This book consists of reprints of articles by the author, giving the results of his experience in the treatment of a limited number of cases of nervous debility by the so-called "Mitchell rest-cure." The principles of this method were first published by Dr. S. Weir Mitchell, of Philadelphia, in a brochure entitled "Fat and Blood, and How to make Them." If credit for a marked discovery in science is due to either of these authors, it is to the latter that we owe it. The present volume simply confirms the statements of Dr. Mitchell. The method of treatment employed is now familiar to every neurologist and to most practitioners of medicine. It consists of confinement to bed, massage, electrical stimulation of muscles, and systematic feeding. We fail to see any special reason why the original contributions of the author should warrant a more extended distribution than the circulation of the journals in which they originally appeared would afford.

BOOKS AND PAMPHLETS RECEIVED.

Presidential and other Addresses by Ed. C. Harwood, M. D., together with Addresses by Professor George T. Elliot, Professor Lewis A. Sayre, Professor Frank H. Hamilton, Professor A. B. Crosby, etc. New York: William R. Jenkins, 1883. Pp. 81. ["Reprints from miscellaneous periodicals."]

Statement of Facts in connection with the Quarterly Report of the Treasurer of the Medico-Legal Society of New York. Prepared for Presentation at the Meeting of September 6, 1882. By Ed. C. Harwood, M. D., etc. New York: W. R. Jenkins, 1881 [*sic*].

By-Laws of the Society of Medical Jurisprudence and State Medicine.

The Rights of the Insane, and their Enforcement. By Clark Bell, Esq., President of the Medico-Legal Society of New York. Pp. 23. [Reprint from the "Journal of the National Association for the Protection of the Insane."]

Secondary Batteries, and the so-called Storage of Electricity. By Roswell Park, M. D., etc. Chicago, 1883. Pp. 16. [Reprint from the "Chicago Medical Journal and Examiner."]

London Water Supply. Report, etc., No. XXV. By William Crookes, F. R. S., William Odling, M. B., F. R. S., F. R. C. P., etc., and C. Meymott Tidy, M. B., F. C. S., etc. London: Wertheimer, Lea & Co., 1883.

The Charge of "Exclusivism" as applied to Homœopaths. By F. H. Orme, M. D. Pp. 8. [Reprint from the "New York Medical Times."]

The Medical and Surgical History of the War of the Rebellion, Part III, vol. ii. Surgical History. Prepared, under the direction of Joseph K. Barnes, Surgeon-General, United States Army, by George A. Otis, Surgeon, United States Army, and D. L. Huntington, Surgeon, United States Army. First Issue. Washington: Government Printing Office, 1883. Pp. xii-986-xxix.

Thirtieth Annual Report of the Pennsylvania Training School for Feeble-minded Children, Elwyn, Delaware County.

The Doctorate Address, delivered at the Fortieth Annual Commencement Exercises of Rush Medical College. By Moses Gunn, M. D., LL. D., Professor of Surgery and Clinical Surgery. Pp. 17. [Reprint from the "Chicago Medical Journal and Examiner."]

NEW YORK, SATURDAY, APRIL 14, 1883.

MEDICAL TESTIMONY.

WE have received a pamphlet entitled "Experts and Expert Testimony," being a paper lately read before the Medico-Legal Society by ex-Surrogate Calvin, as a part of the discussion of a paper on the subject by Dr. Wight. Even in the extemporaneous speeches made by those who follow the practice of the law, to say nothing of their written opinions and arguments, we are accustomed to find a precision of statement far above what is ordinarily met with in medical writings. We infer, therefore, that the pigeon-English with which this pamphlet abounds is not chargeable to the author, but is part and parcel of the slipshod way in which the publications of the Medico-Legal Society are managed. This is the more to be regretted, inasmuch as Mr. Calvin's remarks really embody a good deal that, properly presented, ought to prove of value to medical men when called upon to act as skilled witnesses.

That physicians usually make a poor show on the witness-stand is so obvious to every observant person that it need scarcely be stated. The same is true, however, of other skilled witnesses, or "experts," as it is the fashion to term them, although, perhaps, not to so great a degree. The vicious system that both Dr. Wight and Mr. Calvin deprecate—that, namely, of placing a witness in the position of an advocate or a partisan by the absurd practice of retaining him on the one side or the other—is undoubtedly the chief factor in bringing about the discredit in which skilled witnesses are held by courts, juries, lawyers, and the whole people. Let a man be engaged by one of the parties to an action, and he finds himself at once in the pay of that party; he can not divest himself of the idea that he is bound to make his testimony as favorable for his employers as the limitations of truth will allow. Consequently, in matters of opinion, which seem to him legitimate matters of evidence, and are apt to be so looked upon by all connected with the case, he is naturally, and, we may add, conscientiously, led to so shape his expressions as to give his side of the action the benefit of any doubt he may have in his own mind. We question, however, if more than this can be said.

All this may happen without any moral turpitude attaching to the witness, but, when it comes to those men who are desirous of being considered "experts," who, to use an expression employed in the Guiteau trial, may fairly be termed "professional experts," men who look not alone to discharging their obligations for the time being, but to putting in the most alluring bid possible for subsequent engagements of the sort—men, in short, who seek to make a business of trying conclusions before judicial tribunals, an additional temptation comes into play. Such a man's testimony, we venture to say, is utterly

worthless to the cause of justice; it may even disturb the equitable operation of the law.

But there is another stumbling-block in the way of proper medical testimony—one that, we are persuaded, comes into play far oftener, and one that rises perhaps more frequently before the guileless witness than before the more hardened. We refer to the puerile dread that medical men feel of saying "I don't know." This is easily accounted for by their daily life as practitioners and by the brutal way in which witnesses are commonly examined. It is a bugbear that ought to be faced down, however, and we would impress upon the inexperienced witness that there is no plainer or surer way to avoid falling into the snare set by a crafty cross-questioner than by a frequent resort to the answer, "I don't know."

THE INDISCRIMINATE SALE OF HYPODERMIC SYRINGES.

A *CLEVELAND feuilletoniste*, writing in a recent number of the "Union médicale," takes occasion to state his views as to the precautions that should be taken to guard against the development of the morphine habit in patients for whom hypodermic injections of morphine have been ordered. He admits the propriety of sometimes intrusting the administration of the injections to a friend or relative of the patient, stipulating that the person must be one whose firmness is proof against all entreaties to resort to the medication twice where it has been ordered only once. However laudable may be the desire to save the patient from the necessity of repeated visits by the physician, and the consequent increase in his pecuniary outlay, by thus relegating to a layman a therapeutic measure of this nature, it may be doubted, we think, if the practice is ever a wise one. Apart from the lack of adequate assurance that the deputy's firmness will be equal to the demands made upon it, it should not be forgotten that there are important matters of detail pertaining to the mere method of using the hypodermic syringe—points that, we fear, are too often ignored even by physicians themselves, but that are almost sure not to be comprehended by those who lack a medical training.

The writer in question then goes on to discuss the suggestion, put forward by a correspondent, that the instrument-makers should be restricted in the matter of selling hypodermic syringes to any and all purchasers, and dismisses it with the remark that the syringe itself is harmless, and that it is the indiscriminate sale of morphine that calls for repression. It seems that in Paris, as well as here, pharmacists are in the habit of continuing to fill prescriptions repeatedly and indefinitely, without the order of the prescriber, or even any intimation of approval on his part, but at the mere caprice of the patient. We infer, too, that the case is worse there than here, for it would seem that it is customary for the patient to retain the original prescription, so that he is at liberty to take it to first one apothecary and then another, in case the original dispenser declines to accede to his wishes, thus manifestly widening his chances of doing himself an injury.

This matter of apothecaries dispensing medicine repeatedly on old prescriptions is one that has again and again been

brought to the attention of the profession, and to a certain extent to that of the public, but all to no purpose. It is an abuse that our civilization ought not to tolerate, and it must be that the time is not far distant when measures will be resorted to to control it. For the present, however, we must take things as we find them, and we doubt if it is altogether wise to rely to any great extent on a suggestion to the pharmacists that they should mend their ways. In a matter where there is so little power of control over one of two methods by which a morphinomaniac may achieve his ruin, it certainly seems as if some attention ought to be given to the other. We therefore do not share the view expressed by the French writer, that it is unnecessary to restrict the sale of hypodermic syringes. True, the morphine may be taken by the mouth, but that does not seem to be so attractive to the victim as the injection under the skin.

THE TRAINING OF MIDWIVES.

In our last issue we briefly noted the establishment of a college of midwifery in New York. It seems strange that so large a city, with a considerable proportion of its inhabitants actually dependent upon the services of midwives, should thus far have been destitute of any adequate provision for their education. We therefore look with much satisfaction upon the organization that we have mentioned.

The time has come when the profession must concede to the midwife a legitimate place in the community. It is not many years ago that the women were very few who, if at all above the abject poverty that drove them into a hospital for their lying-in, were not able to avail themselves of the services of a competent physician, but, with the continued immigration that has been going on, all this is changed, and there are now thousands of poor women who, if compelled to make the choice between the attendance of a medical practitioner and a resort to some public charity, would find themselves under the necessity of adopting the latter expedient.

Most of the midwives of New York are of foreign birth and training, if they can be said to have been trained at all, and their ways do not commend them to people of American birth. Hence many a woman that could have afforded the services of one of the guild has shrunk from the experiment, and become a burden for the time being on the community. Now, however, with the facilities that the College of Midwifery promises to afford, we may look to see a class of American midwives arise among us. The result of such a change we can not but consider as likely to prove conducive to the welfare of all concerned. We are quite persuaded that those of our profession who, for one reason or another, practice obstetrics for fees utterly out of proportion to the value of the services rendered will not suffer to any great extent by reason of the establishment of a class of trained midwives, for the latter will draw their support rather from those who now pay no fees at all than from those who are able to employ even the humblest practitioner of medicine.

It is a question if it would not be well to invest the col-

lege, in addition to its educational function, with the power of licensing midwives who are already plying their art here, or who may hereafter come to us from abroad with the intention of doing so. The auspices under which the institution starts seem to us an abundant guarantee that such discretionary and supervisory power could safely be committed to the gentlemen who make up its faculty.

THE PREVALENCE OF SMALL-POX.

SINCE the pandemic of small-pox which raged from 1870 to 1873, the country has been comparatively free from formidable outbreaks of this loathsome disease. Especially has this been the case with the larger cities, which suffered to a very great extent during more or less of the period mentioned—New York less decidedly, however, than Philadelphia, Boston, and Chicago.

During the winter just past, the most notable prevalence of the disease seems to have taken place in Baltimore, and recent accounts from that city show that it is still far from having been brought under entire control, although apparently on the decline. More recent outbreaks are reported from New Orleans and St. Louis, and among smaller communities we have heard of it at intervals through the winter. In fact, with the exception of New England, no great portion of the country seems to have escaped it altogether.

The great lesson to be learned, and that has always to be learned anew, from small-pox epidemics is, that the disease must be fought not only *in esse* but *in posse*; and, although our sanitary authorities in New York have learned it thoroughly, and do not seem to relax their vigilance to such a degree as is witnessed in many other districts, it is yet to be doubted if a vigorous outbreak of the disease would not find this city almost if not quite as ill prepared to cope with its ravages as others that suffered even more severely ten years ago.

It may not be that we are on the eve of another great epidemic, but we can hardly afford to ignore the significance of the fact that the disease is still smoldering at a number of different foci in various points of the country, communication between these points being constant. When we remember how often an outbreak among a tribe of aborigines, occupying a distant and seemingly secluded territory, has proved the starting-point of a widespread prevalence of small-pox, we can not avoid the reflection that our present danger is much more imminent.

A BOGUS MEDICAL COLLEGE AT BAY.

ELSEWHERE in this issue of the journal we publish a judgment lately rendered by the Supreme Court, in the case of the People of the State of New York against certain men representing the so-called United States Medical College. The judgment seems to be final, as we understand that no appeal can be taken to a higher court. The possibilities of the law are marvelous, however, and already the newspapers report that the individuals who figured as defendants in this suit profess themselves confident of their counsel's ability to reopen the

default on which the judgment was founded. We are quite convinced, nevertheless, that, so far as it lies with the courts, the concern stands no appreciable chance of again being clothed with power to create doctors in medicine, legally qualified practitioners, in accordance with its own inclination.

But it is very likely that some legislative jugglery will be tried, with the idea of thwarting the action of the law; for persons capable of taking part in so gross a prostitution of the powers intended to be lodged in educational institutions do not readily give up the remunerative undertaking in which they have embarked. It can not be too often repeated, therefore, or too decidedly impressed upon both the Legislature and the people, that this is not a case in which the prosecution was founded on sectarian feeling, but solely on a genuine desire to protect the community against diploma-mills, and on the self-respect that forbids any honorable profession to look on supinely in the face of a constant degradation of its ranks.

THE ORIGIN OF SPECIFIC DISEASES.

In a paper read at the recent meeting of the British Medical Association, Dr. K. W. Millican expresses his conviction that the greatest advance in our knowledge of the acute specific diseases has been in the attempt to connect them with the growth and development of living organisms, constituting the germ theory of disease. For this theory the antiseptic system of Lister, he thinks, prepared the way. The accumulation of evidence in the rural districts for the past few years he looks upon as pointing to an affirmative answer to the question as to whether these diseases can originate *de novo*. He divides the principal infectious diseases met with in Great Britain into two groups. The first of these includes typhoid and typhus; the second, measles, scarlet fever, and small-pox. Diphtheria, diarrhoea, r  theln, and erysipelas form a connecting link between the two groups. The author records his opinion that any one of these diseases may originate spontaneously, and is then capable of being transmitted by infection. He also believes it is within the bounds of possibility for one form of so-called specific disease to give rise to another form, as scarlet fever to diphtheria, or *vice versa*. His reasons are: first, that, as they must have originated before, so they may originate again; an objection to which would be that it is not in accordance with the general plan of development in nature for forms to reappear *ab initio*. The answer to this objection is as follows: Among the higher members of the animal and vegetable kingdoms, by ranging the conditions of existence the cultivator may reproduce, and render more or less permanent, a variety already existing. But the development of a species, though it may occur once, is, by the very complexity of its conditions of transformation, almost prohibited from ever occurring again. In the lowest forms of animal and vegetable life different and more elementary conditions obtain, and the inference is natural that the conditions necessary to produce a specific or permanent variation are few and simple, and hence more likely to concur. The probability of this event, it is suggested, is in proportion to the length of time occupied by the life-history of the organism. Hitherto attention has been too much concentrated upon known and recognized types of zymotic diseases, but accurate observations of abnormal cases will throw most light upon this problem. These cases may be classed under three heads. 1. Where disease of one type appears to produce disease of another type. 2. Where from a common source two or more distinct diseases appear to take origin. 3. Cases of indeterminate type, and such

as present gradations. As an illustration of the first proposition, two girls who suffered from habitual rhinorrh  a stayed at home a week after their school had been closed on account of scarlet fever, and then entered another school. Within a week an epidemic broke out in the latter school, the patients presenting every conceivable variety of diphtheria and scarlet fever, with and without rash. As an illustration of the second class, a young laboring man was attacked with typical and severe typhoid fever. Diphtheritic patches soon formed on the tonsils and pharynx. On the twelfth day of the fever abdominal rose-spots appeared. At the same time a rash of a typhous character appeared on the pectoral regions. The temperature rose to 105   F., but fell three days later to 100   F., and a crop of papules appeared on the buttocks and wrists. These became vesicular, and finally pustular, the fever again appearing with suppuration. The only causes discoverable were the ordinary unsanitary conditions. The clew to such cases, in the author's opinion, lies in the doctrines of the development and origin of species. Given life, if the conditions which determine a certain line of development coexist at different times, why, he asks, should not the same line of development recur? The soil in which disease is developed, varying as it does with the constitution and susceptibility of races and individuals, will call for greater investigation than it has hitherto received.

Another important question is, Does indefinite incubation occur in well-marked and typical cases, or only when there is a struggle for existence? He summarizes as follows: 1. The processes of development and the origin of species are still going on in diseases. 2. It is assumed that organisms not essentially disease germs may become so on introduction within the human economy; that the form taken by the disease depends on the pabulum selected by the germ, and that specific characters are developed in the germs in course of time. 3. This process accounts for the *de novo* origin of the so-called acute specific infectious diseases, for abnormal cases of these diseases, and for changes of type in transmission. 4. This process is probably evolving, through the many unclassifiable and abnormal cases, fresh specific diseases for the future. As to lines of research, the author would suggest the following: 1. It is to abnormal rather than to normal cases that we are to look for the future settlement of the question. 2. In cases of infectious disease where no origin can be traced, special attention should be paid to any irregularities indicating imperfect or progressive development. 3. In cases of seeming change of type, special inquiry should be made into hereditary predisposition. 4. Further chemical, microscopical, and spectroscopical examinations of the blood should be made in fever cases, the results of typical and abnormal characters being compared. 5. Special attention should be paid to cases and epidemics of such affections as form prominent symptoms in certain well-established diseases; e. g., infectious sore throat and the question of its development into scarlatina or diphtheria.

SANITARY ARCHITECTURE.

PROFESSOR H. ROBINSON recently addressed the Sanitary Institute of Great Britain, touching upon many important points of sanitary engineering and architecture. He said that not one quarter of the dwellings of all classes were free from dangers to health due to defects with respect to drainage, water, or ventilation, which could have been avoided at the outset. An increasing public interest in such matters would enable sanitary authorities to enforce regulations more thoroughly. In cases where a zymotic disease arose from sewer gas, infected water, or other improper conditions about a house, the physician in attendance should notify the local authorities, and the

house should be marked as unsanitary upon the official map. Whenever a death occurred from typhus or typhoid fever arising from preventable causes, an autopsy should be made. The lecturer also insisted upon the very important item that all new houses, before being let, should be certified by the local authorities as sanitarily complete. We may add that, if that precaution were still further extended, requiring landlords to furnish, in all cases, certificates from the local board of health that the houses rented were in a proper sanitary condition, with a heavy penalty attached to its non-fulfillment, it would awaken to a sense of duty certain individuals who never arrive at that condition until forced by the law. In addition to this, it would effectually prevent a great deal of sickness. The local regulations in regard to such matters in Chicago, says the "Sanitary News," are excellent, but, as they have been in effect only a year, it is yet too early to notice the great benefit which must result.

Proceedings of Societies.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A STATED meeting was held October 28, 1882, Dr. B. W. McCREADY Chairman for the evening.

INTestinal CANCER.—Dr. FORDYCE BARKER narrated several cases as possessing certain clinical features of interest. [His remarks will be found in this journal for January 20, 1883, p. 64.]

Dr. H. B. SANDS said there could be no question but that cancer did sometimes occur primarily in the rectum in women. He had such a case under care at present in a lady forty-five years of age. He had also seen a similar case with Dr. Jenkins in which the diagnosis was verified at the post-mortem examination.

Dr. OTIS remarked that he once operated in a case of primary cancer of the rectum in a woman.

LILY OF THE VALLEY AS A THERAPEUTIC AGENT.—Dr. S. O. VAN DER POEL had noticed in late French journals that extract of lily of the valley was used largely in France in the place of digitalis, because of the tendency of this drug to produce nausea and sometimes to have a cumulative effect upon the system. In the case of a man who lost consciousness while driving in the park, and was found to have mitral stenosis and insufficiency with irregular action of the heart, Dr. Van der Poel at first found digitalis with quinine of benefit. Some months afterward the man returned, looking very pale, with loss of appetite, the heart feeble, the limbs edematous up to the knees. Feeling that it was not best to push the use of digitalis further, the fluid extract of the lily of the valley was substituted in eight-minim doses twice a day. Marked improvement soon took place. The edema disappeared in eight or ten days, the heart's action became more regular, and for some days afterward he had seen the patient riding out in the park. Also, in a case of internal cancer accompanied with œdema of the extremities, lily of the valley was given with the result of causing the œdema to disappear; over two months had elapsed, and, though the anæmic condition was extreme, there had been no reappearance of œdema, the lily of the valley having been given daily.

Dr. F. DELAFIELD had used the drug in a number of different cases, as in organic heart disease, chronic Bright's disease, feebleness of the heart in fever and pneumonia. It made the heart's action more regular and slower in a certain number of cases, and the general condition of the patient improved very much. He had found, like Dr. Van der Poel and Dr. Barker, that there was a great difference between different patients as to the

size of the dose demanded. For some patients, five drops of the fluid extract every three hours answered the purpose, while other patients required drachm doses. The most marked benefit which he had derived from it was in the case of a woman over seventy years of age, who was apparently about to die of pneumonia. He took the risk of stopping alcoholic stimulants altogether, and gave her twenty-drop doses of the fluid extract of lily of the valley every three hours, and after this change was made the patient did very well indeed.

THE EFFECT OF IODIDE OF POTASSIUM UPON ANEURYSMS.—Dr. R. F. WEIR raised this question by relating the following case: A lady, sixty years of age, had suffered for two years with aneurysm situated low down in the neck on the right side. When he first saw her, the aneurysmal tumor was of about the size of the large end of a hen's egg. It was pulsating quite strongly, and gave rise to a good deal of distress in the head on that side. There was an obscure history of syphilis in early life. It was not deemed advisable to operate, and she was placed upon the iodide of potassium, ten grains three times a day, with the effect of a diminution in the size of the tumor, lessening of the pulsations, and disappearance of the head symptoms. No consolidation took place in the aneurysm. A similar result occurred in another case in which there was no history of syphilis, but the patient passed from under observation, and it was not known whether the result was permanent or not. The probable explanation of the effect was lowered heart tension due to the action of the potassium salts, and not increased coagulability of the blood, as was once supposed.

Dr. DELAFIELD remarked that this was the ordinary treatment of aneurysm of the arch of the aorta. Great improvement resulted in some cases, but not in all. As stated by Dr. Weir, the probable explanation was that suggested by Balfour, namely, the effect produced by the drug upon the action of the heart, and not increased coagulability of the blood, for post-mortem examinations often showed that no coagulation at all had taken place.

Dr. G. G. WHELOCK asked whether any of the members had obtained good results in the treatment of abdominal aneurysm by this method. He had not.

Dr. DELAFIELD recalled a case of aneurysm of the abdominal aorta in which the result of the iodide of potassium treatment was markedly beneficial. The trouble in such cases usually was that the vertebrae had become eroded before the patients presented themselves for treatment.

Dr. R. WATTS remembered to have seen two or three cases treated by the administration of iodide of potassium and by rest, and he thought the latter was an important part of the treatment. In one case little apparent benefit followed the use of the drug until after the patient confined himself to bed for some time, and then he improved. In another case the patient remained abed and took the salt and got better; she then got up and moved about, continuing to take the medicine, and had a relapse, and again obtained relief by returning to bed and taking the medicine.

Dr. SANDS mentioned the case of a woman with supposed sacculated aneurysm of the innominate artery in whom the iodide of potassium treatment afforded great relief. The tumor diminished in size instead of growing, and the pulsations became less marked. There was no evidence of consolidation of the contents of the sac to any extent. There was no history of syphilis.

RAPID DEVELOPMENT OF STONE IN THE BLADDER.—Dr. OTIS related the following case as bearing on this question: A few weeks ago a man presented himself who had had a history of urinary trouble for about sixteen years. It was characterized chiefly by frequency of urination and very little pain. He was

examined repeatedly for stone, but none was found. The meatus was divided for possible reflex trouble, but without relief. Finally he became unable to pass his urine without the aid of a catheter. Some months afterward, while using a French gum catheter, it broke, and about four inches of it remained in the bladder. Just before this the patient had been examined for stone by a competent surgeon, and none was discovered. Two weeks after the accident, Dr. Otis saw the patient. He was suffering from frequent urination with pain. Dr. Otis introduced the lithotrite and thought he struck the piece of catheter; was quite certain he had struck nothing else. But, on opening the jaws of the instrument and closing them, he found that he grasped a stone nearly an inch in diameter. He made several crushings, and removed it with Bigelow's apparatus. It was an ordinary recent phosphatic calculus. After several attempts he succeeded in drawing out the piece of catheter, which was found slightly incrustated with calculous material. In this case the active symptoms of stone came on only after the breaking of the catheter. Repeated examinations previously failed to detect any. It was probable, therefore, that this large calculus had formed within three or four weeks' time. He remembered a case where he made section through the rectum into the bladder in a rebellious case of cystitis, and introduced a tube for the passage of urine. Within a few days a very considerable amount of calculous material formed on the tube and made it difficult of withdrawal. This was repeated several times in the course of the case. Relief failed after about six weeks' trial, and apparently on this account.

Dr. SANDS remarked that he thought it quite likely stone could form within a few weeks, but this was not perfectly evident in Dr. Otis's case. Dr. Otis himself had failed to discover it in the first place, and, therefore, it might have been overlooked some time before, and still have been present.

Dr. A. C. POST remembered that when it was customary to treat strictures by external urethrotomy, and to leave the catheter in for some time, the instrument would, within a few days, become pretty well incrustated with calculous matter.

Dr. OTIS remarked that when he related this case to Dr. Peters, the latter said he had seen but one case in which there was known to be very rapid formation of stone. It was in the case of a relative, and within two weeks the stone reached the size mentioned by Dr. Otis.

Dr. WEIR had removed a hair-pin from the bladder of a girl six weeks after its introduction, and the amount of phosphatic material which had formed on it was found to weigh forty-five grains. He had seen a case with Dr. Abbe in which the amount of phosphatic material deposited on a foreign body, which had remained in the bladder of a man for six months, was equal to one hundred and seventy or one hundred and eighty grains. He thought that the greater number of so-called re-formation of calculi owed their appearance to a nucleus of an old calculus left in the bladder.

ABSCESS OF THE LIVER.—Dr. A. B. BALL related the following case as showing the readiness with which even a very large abscess of the liver might be entirely overlooked during life: A man was brought to St. Luke's Hospital, said to have typhoid fever. There was no evidence of this disease, however, except the presence of fever. The patient was also delirious. Both pleural cavities were about half full of fluid, and there was also some pericardial effusion. The symptoms were not sufficiently urgent to demand tapping. He lived but a few days after admission. There was found, at the autopsy, besides fluid in the pleural and pericardial cavities, an abscess of the liver containing about a quart of pus. The liver was not particularly enlarged. The abscess had been entirely overlooked during life, and, indeed, it was difficult to understand how it could have been

recognized under the circumstances. In connection with this case Dr. Ball referred to that of a man at the same hospital who recovered from an abscess of the liver, the first case of the kind which he had known to occur at the hospital. The patient's general health was pretty fair, but he was emaciated, rather sallow, and complained of pain over the region of the liver, which was evidently due to a perihepatitis. Abscess being suspected, he was aspirated at the seat of the pain, but no pus was withdrawn. After two or three weeks, bulging occurred between the ninth and tenth ribs on the right side, and there was an obscure sense of fluctuation. He was again aspirated, and this time about a pint of blood-colored pus was withdrawn. The cavity rapidly filled again, and after two days the abscess was laid freely open and dressed with Lister dressing, excepting the spray. A very large amount of pus discharged, and the man entirely recovered. No decomposition of the pus took place, and there was at no time any elevation of temperature except just before the second aspiration was made.

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held February 6, 1883, Dr. C. C. LEE, President, in the chair.

FLAT SPONGES FOR USE IN ABDOMINAL SURGERY.—Dr. W. T. LUSK presented some soft, flat sponges, and briefly alluded to their advantages in abdominal surgery, especially in retaining the intestines in position, and preventing the escape of liquid material into the abdominal cavity. These sponges being but little in demand, it was difficult to obtain them at the drug-stores. In order to meet the special wants of ovariologists, Mr. Angelo, corner of Thirty-first Street and Fourth Avenue, had sent for a large supply.

MODIFICATION OF FREUND'S OPERATION FOR REMOVAL OF THE UTERUS.—Dr. W. G. WYLIE, by invitation, narrated a case as follows: The patient, a woman, sixty-five years of age, who had never borne children, was sent to him last summer, suffering from uterine hæmorrhage of about one year's duration. The menopause had been passed about nine years before. The patient was very nervous, but well-nourished and apparently in good health. The hæmorrhage of late had become more severe, and she suffered from neuralgic pain extending upward on the right side, in the neighborhood of the uterus. Upon physical examination, the vagina was found to be small, the cervix rather large, and the uterus three and a half inches in depth. Considerable hæmorrhage followed the withdrawal of the sound. Slight dilatation was made, and the uterine cavity was curetted, bringing away quite a mass of broken-down tissue, which was not examined microscopically. The case was supposed to be one of so-called granulations of the lining membrane, or possibly of malignant disease. Hæmorrhage ceased for two months after the curetting, and pain was relieved to some degree. The patient was then seen also by Dr. Sims, who believed that she was suffering simply from granular degeneration of the lining membrane of the uterus, and that Dr. Wylie had probably failed to remove all of the granulations at the former curetting. Dr. Wylie then dilated the cavity a second time, and curetted it thoroughly. Dr. Welch examined a piece of tissue, about the size of a pea, which had been removed, and pronounced it undoubtedly epithelioma. Pain and hæmorrhage were again largely relieved for about a month after the second operation. The patient consented to an operation for removal of the uterus about three weeks ago, and entered Bellevue Hospital. Dr. Lusk and Dr. Polk saw her in consultation with regard to whether it were best to remove the uterus through the vagina or through the abdominal walls. As the vagina was atrophied, and as it would be difficult in operating by that method to de-

termine, as the operation proceeded, whether the tissues outside of the uterus were involved in the cancerous disease, Dr. Wylie decided to make the abdominal incision. Expecting to meet with considerable fat, and, on account of senile atrophy, with immobility, as the operation proceeded, it was thought impossible to carry out Freund's method perfectly, and the following procedure, which it was believed would require not more than half the time, was adopted. The incision extended from the umbilicus down nearly to the pubes. The uterus was moderately pressed against the abdominal wall by a Sims's retractor, introduced into the cavity, and held by an assistant. On account of the bulkiness of the fat and the distended intestines, it was necessary to lay the latter on the abdominal wall. The body of the uterus was then grasped with a strong forceps, and turned from side to side by another assistant as occasion required. By means of a simple curved needle in a holder held in the right hand, while the left served to receive the point of the needle and protect the intestines, etc., two ligatures were tied round the broad ligaments, one just outside of the ovary, dipping below the round ligament, and the other nearer the body of the uterus. Afterward a cork, fastened to the end of a stick, was then passed up the vagina, and pressure was made in Douglas's cul-de-sac, lifting the uterus upward. A trocar was passed from above down through the tissues into the cork held firmly below in Douglas's cul-de-sac, and the end of the cannula was brought out at the vulva. Beforehand, a long loop of very strong silk (soft wire would have been better) had been fixed in a hollow piece of hard rubber just the length of the vagina, so that the lower ends of the loop could be attached to an écraseur, and made to tighten the loop at the upper end of the tube where it came out of the tube on its anterior surface just below the end. By means of a small wire passed down through the cannula of the trocar, this loop was drawn up through Douglas's cul-de-sac into the abdomen, and held by an assistant, while the broad ligaments were cut between the ligatures placed in them, and the bladder separated from the anterior wall of the uterus down to the vaginal junction. The loop was then passed over the body of the uterus and slipped down to the vagina below, while it was being tightened by the écraseur, worked by an assistant at the outlet of the vagina. At the same time, the uterus was held upward by strong forceps clamping the fundus. The object of this loop ligature being to ligate all vessels not included in the outside ligature, first put in the broad ligaments and to grasp the upper end of the vagina just below the cervix, so that, when the whole uterus was enucleated, there would be no bleeding points, and only three ligatures left. When the loop was tightened, the bleeding was entirely stopped. By means of curved scissors, the uterus was readily cut off just above the loop ligature. It was then discovered that a small part of the cervix had been included in the loop, and the uterus cut off just at the vaginal junction. There was no bleeding at this time; but, in attempting to elevate the stump with a large pair of forceps, the loop ligature slipped up over the stump. It was withdrawn from the vagina and the cork plug put in, and the stump pushed upward, and, the cork being quite large, the upper end of the vagina was put on the stretch and distended. While the stump was held up and steadied, by means of the same curved needle used on the broad ligaments, armed with a ligature and held in Sims's needle-forceps, two ligatures were passed on either side of the stump, dipping down into the vagina in close proximity to the cervix. After these were tied and the cavity cleansed, one bleeding point was found in the left broad ligament, a short distance from the ligature just tied. A third ligature was passed from before backward with the curved needle, and, when tied, all bleeding ceased. The cork plug held by the assistant pushing up the stump made the passing of

the ligatures easy, and lessened very much the risk of including the ureters in the ligatures.

The uterus, upon examination, was found entirely free from cancer, except the lining of the body, which was pretty well covered by a growth that filled and somewhat distended the cavity, and the point of excision was full half an inch or more below the lowest part diseased. The small part of the atrophied cervix left as a stump was found perfectly healthy, and it was decided not to remove it. After waiting some time, to be sure that no points were bleeding, a drainage tube was put in and the wound was closed, and the operation completed in about one hour and forty-five minutes, with the patient in good condition. Three hours later she came out from the anæsthetic, and had a good pulse of 96. She was clear mentally, and did perfectly well during the first twenty-six hours after the operation, the temperature not rising above 101° Fabr., nor the pulse above 108. At the end of that time she became slightly delirious, picked at the bed-clothing, and complained of dryness of the throat; there was slight dilatation of the pupils, the respiration and the pulse became more rapid, and she died thirty-six hours after the operation. The patient, being addicted to the use of opium, received one hundred minims of Magendie's solution in the twenty-four hours, and, by mistake, also a twelfth of a grain of atropine in divided doses, which might in part account for certain of the symptoms, but Dr. Wylie could hardly believe it could have been the cause of death, nor was anything found at the post-mortem examination which would account for the fatal issue. Peritonitis was not apparent, and there had been no hæmorrhage. Dr. Welch had examined the specimen, and pronounced it epithelioma.

Dr. Lusk remarked that there was one important point connected with the case which Dr. Wylie had not mentioned, namely, that it was one of undoubted primary epithelioma of the uterus—a condition which some pathologists of large experience doubted ever existed. Freund found that by means of pressure with the colpeurynter for a week before the operation the uterus could be elevated even as high as the umbilicus. At the time of the operation the ordinary vaginal tampon was introduced, and, with the uterus thus lifted above the brim of the pelvis, one of the difficulties of extirpation was removed.

Dr. WYLIE said he could fully appreciate the advantage of the procedure, and, while he had not then heard of its being practiced by Freund, he thought of resorting to tampons in the present case to render the uterus more movable, but she was so nervous that he decided not to do so. During the past few months he had several opportunities to observe how quickly and decidedly forcible traction upward on the uterus during operation was followed by shock, and he thought that this might be very much lessened, if not obviated, by getting the uterus accustomed to being forcibly elevated before operating.

Dr. J. E. JANVRIEN remarked that it was a difficult matter to apply the third ligature in the manner practiced by Freund for controlling hæmorrhage from the uterine arteries, whereas the method adopted by Dr. Wylie would seem to be very easy of application and quite efficacious. In a case in which he performed the operation he made use of the former method, and experienced considerable difficulty in carrying it out. In reply to a question by the President, he said that his own patient died at the end of thirty-six hours.

The PRESIDENT remarked that he knew of no other case in New York in which the operation had not terminated fatally. The danger of a fatal issue in these cases was enhanced by the fact that, owing to the usual effects of malignant disease upon the general health, the patient was less able to withstand primary and secondary shock than where the operation was done for non-malignant disease.

The proper field for hysterectomy, as had been suggested by Dr. Polk at a previous meeting of the society, seemed to him to be limited to such cases as sarcomatous growths, where the disease was confined to the uterus itself and was not in danger of recurring after the operation, and where the patient's general condition was not depraved from the constitutional effects of the disease, and was better able to withstand the dangers incident to the operation itself. The mortality attending Freund's operation, as reported by all surgeons except by the author himself, had been so great that American physicians had little confidence in it.

NEPHRECTOMY IN A CASE OF SINGLE KIDNEY: METHODS OF DIAGNOSIS.—Dr. POLK narrated a case of this sort. [Dr. Polk's paper will be found in this journal for February 17th, p. 171.]

The case was made the special subject for discussion at the next meeting of the society.

HENRY J. GARRIGUES, M. D.,

B. F. DAWSON, M. D.,

FRANK P. FOSTER, M. D., *ex-officio*,

Committee on Publication.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A REGULAR meeting was held January 11, 1883, Dr. JAMES TYSON, President, in the chair.

CONDYLOMATOUS TUMOR OF THE LABIUM.—Exhibited by Dr. NANCREDE for Dr. C. M. SELTZER. Mrs. ——— contracted syphilis nine years ago from her first husband. Has had specific treatment at intervals, but never prolonged beyond a few weeks each time. Condylomata and ulcerations around the vulva, anus, and perineal region were first noticed about three years ago. She first came under his observation and treatment June 1, 1882, at which time symptoms of her disease were very pronounced, such as cachexia, nervousness, nocturnal headache, ulcers on various portions of the body, numerous condylomata, of which the specimen exhibited was the largest, being a cauliflower-like excrescence springing from the left labium majus, having a pedicle about two and a half inches broad. The clitoris was hypertrophied, forming a knob one inch in diameter. There was urinary incontinence, and, consequently, severe excoriations of the external genitals. Potass. iod. and hydrarg. bichlorid. were given, upon which there was pronounced systemic improvement. Local treatment failed to remove the condylomata; hence, on the 13th of November, two double ligatures were passed through the pedicle of the largest so as to divide it into three parts; they were then tied tightly, and the mass removed and the stump cauterized with nitric acid. The clitoris was so sensitive, even under profound anesthesia, that it was thought best not to remove it. The patient made a good recovery in ten days, including the cure of the urinary incontinence. Her second husband, to whom she had been married about six years, had no evidence of having syphilis. Her only child by her first husband had stricture of the rectum and obstinate fissure of the anus, improvement of which only began upon the recognition of their specific origin, and the consequent line of treatment. Dr. Nancrede suggested that this specimen be referred to the Committee on Morbid Growths, since two somewhat similar specimens, which were myxomatous fibromata, had been presented by Drs. Formad and Baer. Although not due, as in this instance, to the irritation of some sore or abrasion by the discharges, etc., in a syphilitic, yet probably their histological structure was identical.

SMALL TUMOR OF THE HEAD OF THE PANCREAS.—Presented by Dr. E. T. BRUEN. The mass herewith exhibited occupies the head of the pancreas, and is about as large as a pullet's egg—i. e., about two and a half inches in diameter. When re-

moved from the cadaver, it was closely adherent to the common bile duct. The growth is of a colloid nature, but its histological character is as yet unsettled by microscopic examination. There were no secondary deposits in any other viscera, as is the rule in colloid growths. The patient was a male, aged sixty five years. For two years prior to date of his death there had been intermittent attacks of jaundice. This had been attributed to catarrh of the biliary duct, which had developed itself during an attack of malaria. The case was under his care for two months. At first the symptoms of chills and fever led to treatment for malaria, but, as the jaundice gradually deepened, treatment for the supposed catarrhal state of the bile duct was instituted. The utility of a well-directed and usually successful treatment was the special indication of some more substantial cause. Hepatic trouble or biliary calculi were readily excluded in this case, but there was nothing to fasten suspicion on the pancreas. There was constipation, with clay-colored stools. There was a febrile movement of a hectic type—the so-called hepatic fever, accompanied by irregular chills. The intestinal indigestion, so valuable a symptom in many cases of pancreatic disease, was not marked. Indeed, without exception, the negative results of the clinical record were of the most discouraging character. The case was presented because each case of pancreatic disease ought to be recorded, so that many cases viewed collectively might contribute to the clearness of a future distinct picture of pancreatic disease.

Dr. FORMAD said that he had now on record the notes of five or six cases of cancer of the pancreas with marked jaundice where he had made the autopsy. It seemed to him that the jaundice was most persistent in primary pancreatic carcinoma from pressure on the bile duct. He was present at the autopsy of this case, and did not think that the tumor was carcinomatous, as there would then probably have been secondary growths in the liver. The growth was probably a cystic colloid.

Dr. BRUEN would like to call the attention of the society to the fact that he had, about a month ago, presented a specimen of carcinoma of the pancreas, and had then referred at length to some forty cases of jaundice due to primary carcinoma of the head of the pancreas, lately reported by another observer. From these records it was demonstrable that jaundice was an invariable symptom of primary hard carcinoma of the head of the pancreas, while it was uncommon when the disease was second ary, or affected other parts of the organ.

DIAPHRAGMATIC HERNIA.—Exhibited by Dr. JAMES TYSON. The patient from whom these specimens were removed was a German, between twenty-seven and twenty-eight years of age. He first consulted Dr. Tyson June 21, 1880. He had then been ailing since February, 1878, and had been unable to work in that time. At the date referred to he was stretching, when his wife suddenly pretended to tickle him. He quickly threw down his arms, and at that moment felt a sensation of "pain on the left side in the neighborhood of the heart." At the same time he felt faint and cold. In five or ten minutes these sensations passed away, but he remained very much frightened. When first visited, he complained of shortness of breath and beating of his heart, although the latter was better when he was quiet. He could not even walk across the floor without becoming completely out of breath, but he said he was not short of breath when the accident first occurred. He had also a peculiar puffing expiration, which did not occur, however, with every act of expiration, but once in four or five. This was so characteristic that one of his friends, to whom Dr. Tyson sent him, spoke of him as his "puffing German." There was no cough. Physical examination revealed, on inspection, almost total absence of movement of the chest-wall in the upper half, the respiration being almost purely abdominal. The upper percus-

sion border of the heart corresponded with the junction of the third rib with the sternum, and the right border with the middle of the sternum. The apex beat was in its normal position, but was more diffuse than in a strictly normal state. Pulmonary percussion appeared normal except below the left scapula, where resonance was less than in the corresponding situation in the right side. Vocal fremitus was, however, impaired over the whole of the left lung. There were no abnormal cardiac murmurs. His pulse was 72 after the examination was over. He was treated at various times with digitalis, bromide of potassium, chloral, tonics, etc., and even a blister was put over his heart, with the view that there was some cardiac or pericardial affection, although the physical signs were wanting. There was no improvement, although at times the dyspnoea, which was the most distressing symptom, seemed somewhat less; but it always interfered with any exercise whatever. He would walk sometimes half a mile with great difficulty. Notwithstanding this, he was encouraged to take exercise. His sleep was unsatisfactory; he would dream, and wake up in a great fright. He could always lie upon his left side with more comfort than upon his right. He continued under observation for a year. In the latter part of August, 1881, he seemed a little better. After that Dr. Tyson heard nothing of him until he learned of his death, which occurred December 15, 1882, from obstruction. At the autopsy it was ascertained that about twenty inches of the large intestine, with its corresponding mesentery and almost the whole omentum, had ascended through the œsophageal opening of the diaphragm into the left pleural sac, encroaching upon the space occupied by the left lung until the latter was compressed into the apex of the left pleural sac and was reduced to a cylindroid mass about fifteen centimetres in length and half as many in diameter. There was no hernial sac, the opening being that for the œsophagus. The case would, therefore, be technically called one of *hernia diaphragmatica spuria*. The heart was displaced to the right, but was otherwise normal; the liver was slightly fatty, but the other viscera were normal. It is not unlikely, at the moment referred to in the history when the patient threw down his arms, that a small portion of the omentum or mesentery slipped through the œsophageal opening, and that subsequently, and more or less gradually, the vacuum tendency of the pleural sac in each act of respiration caused the remainder of the mass to be drawn in until the entire cavity was occupied. This accounts for the fact that there was no dyspnoea at the beginning, but that it gradually increased as the thoracic space was intruded upon. In volume lxxxi, 1882, of Virchow's "Archiv" there was an exhaustive article on Diaphragmatic Hernia, in which two hundred and ninety-one cases are collated. In a somewhat hasty examination of this paper Dr. Tyson had been unable to discover a single case so long under observation as this—nearly four years. Many cases were discovered at the autopsy, and had been unsuspected; others were congenital, and others were traumatic.

Dr. FORMAD related some facts confirmatory of the history given by Dr. Tyson.

Dr. BREN asked if there had been any hiccough. If so, was there any dysphagia with solid food? Finally, did the physical signs suggest pneumothorax?

Dr. ROBERTS made some remarks with reference to the diagnosis and to the possibility of laparotomy in similar cases. He also asked whether the symptoms just preceding death were those of strangulation.

Dr. DAVIS referred to thirst as a prominent symptom, according to Lawrence.

Dr. TYSON replied that Dr. Formad had told him that there was decided hiccough. There was no true tympany with the absence of the vocal fremitus. Nothing gave rise to any sus-

picion of its true nature. Thirst was marked. There was no dysphagia.

ULCER OF THE STOMACH IN THE ANTERIOR WALL: ADHESIONS TO THE ABDOMINAL WALL; HÆMORRHAGES AND PAIN: DEATH FROM MORPHINE HABIT.—Exhibited by J. H. MUSSER, M.D. He was indebted to Dr. J. Henry Musser, of Lancaster Co., for the privilege of presenting this specimen. The following history was abstracted from his notes: J. J., aged seventy-one years, millwright. Fourteen years before his death he was attended by the doctor for hæmatemesis, occurring after three days of nausea. Over a pint of blood was vomited, and considerable was discharged by stool the next day. In ten days he returned to work, and enjoyed good health for two years, with the exception of occasional attacks of indigestion. Then a recurrence of nausea, followed by a profuse discharge of blood per anum, occurred. He made a full recovery, but pain after eating was now noticed. Two years subsequently he bled very much from a wound of the foot; was much prostrated thereby. This was succeeded by severe pain after eating, with marked epigastric tenderness. The constant use of narcotics alone gave him relief. November, 1873, he was again under Dr. J. Henry Musser's care, and was treated for gastric ulcer, without any avail, save when he exhibited narcotics. He resorted to the use of morphia, and continued its use during the remainder of his life. Change of diet did not influence the pain, and he partook of a laborer's fare. In 1877, a small tumor to the left of and several inches above the umbilicus—hard, tender, and apparently involving the abdominal wall—was discovered. For several years he worked in a country saw-mill, using one drachm of morphia a month. Heavy lifting aggravated his pain. August, 1882, the doctor was again called in, to find the patient confined to bed, much emaciated, and with complete anorexia. Death took place three weeks later, during which time he had taken no nourishment, but had used morphia freely. He took the drug from habit, as his friends thought that he suffered but little pain. The only anatomical alteration noted at the autopsy was the change in the stomach. The organ was enlarged and contracted (hour-glass) toward its fundus. The anterior wall, one third of the distance from the fundus, and at the point of constriction, was adherent to the abdominal parietes to the left of the median line, three inches above the umbilicus. Opposite to the point of adhesion in the mucous membrane there was a small ulcer, two lines deep and six in diameter, with clean-cut edges, a healthy floor, and surrounded by cicatricial tissue for a radius of one inch. Undoubtedly the ulcer would have healed entirely had not the morphia habit cut off the patient.

Remarks by Dr. J. H. MUSSER: It is plausible to theorize that the first hæmorrhage, taken with the profuse foot hæmorrhage, was due to the patient having been of a hæmorrhagic diathesis, and that the second gastric hæmorrhage was from the same cause, and was attended by a hæmorrhagic infarct, with subsequent development of the ulcer. Especially is this possible as it was only after the second hæmorrhage that pain occurred, and this symptom is never absent "except in cases which run a rapid course" (Da Costa).

Dr. NANCREDE related the case of a "bleeder" then under his care, a female infant only thirteen months old, where death was imminent from epistaxis.

Dr. DUNN made some remarks on the general subject of hæmophilia and its treatment.

C. B. NANCREDE, M. D., Recorder.

ESMARCH'S BANDAGE AND MALINGERING.—It is related in a recent work by Dr. Deiblich, of the Austrian army, that Esmarch's bandage has been used in the case of a man who feigned a contracture of the leg of six years' standing, with the result of detecting the imposture.

New Inventions, etc.

A NEW CAUTERY BATTERY.

[We are indebted to the "Scientific American" for the following abstract, from "L'Électricien," as well as for the cut with which it is illustrated.]

M. Chardon, a French manufacturer of electrical apparatus for medical and surgical purposes, has recently devised a pile which is specially designed for the cautery, doing away with some of the serious inconveniences inherent in other piles of the kind that have hitherto been employed. In this new apparatus, which is shown in the annexed cut, the elements are inclosed in an easily transportable box or case, and are so constructed that there shall be no danger of the fluid's spilling. It takes but a few minutes to mount and use the cautery, and but a few minutes also to close up the apparatus again to make it transportable.

The apparatus consists of a box, whose cover, S, and one side, R, are hinged, and within which is fixed a metallic support formed of three vertical columns united at their upper extremity by a horizontal crosspiece. Into the middle column, which carries a thread, enters a screw, while into the other two, which are smooth, enter two cylinders, H, that act as slides. This screw and these slides support, by means of a properly arranged device, a wooden tablet on which are fixed all the pieces that are necessary for the working of the apparatus. The head of the screw traverses this tablet and terminates in a wheel, C. It follows, from the well-known properties of the screw, that the tablet, which can not revolve because of the two slides, H, may be made to rise or descend by turning the wheel, C, in one direction or the other. Beneath the tablet and toward the extremities, at F, are situated the zincs and carbons. There are three of the former on each side, with four alternating carbons. These seven plates together do not take up much space in the box, but leave room for two quite thick sheets of rubber, I I, and four ebonite troughs. These latter are of different heights, those (L) containing the exciting liquid (solution of bichromate of potassium and sulphuric acid) being nearly as high as the external case, and the others, M, being of about half the height.

When it is desired to use the pile, the tablet is raised by revolving the screw, and the troughs, L, half full of liquid, are placed against the extremities of the box and secured in position by means of the troughs, M. Then, by revolving the screw in the opposite direction, the tablet is made to descend, and the zincs and carbons are caused to enter the liquid gently without splashing. If the circuit is closed, the current then begins to pass. The intensity of the latter is regulated by plunging the zincs to various depths into the liquid.

When the operation is terminated, and it is desired to carry the

pile to another place, the tablet is raised high enough to free the extremities of the carbons and zincs, and the respective positions of the troughs, L and M, are changed. Then, by reversing the motion of the screw so as to cause the tablet to descend, the sheets of rubber, I, are pressed against the edges of the troughs containing the liquid with sufficient firmness to form hermetical covers to them. The case may then be closed preparatory to removal. It may be easily seen that no liquid can flow out, owing to the fact that the troughs that contain it are tightly closed, and that the small portion that drips from the zincs and carbons can not injure the rest of the apparatus, inasmuch as it is caught in the troughs, M.

The zincs and carbons employed are about fourteen centimetres in width in each direction. The three zincs on each side, as well as the four carbons, are united for quantity in such a way that two elements of wide surface are obtained. The terminals that are observed on the upper side of the tablet permit of employing at will one or the other of the elements only. On the contrary, the two elements mounted for tension may be used by attaching the conducting wires to one of the terminals of each of the elements, communication being established on another hand by a wide band of metal.

The carbons are platinized, and toward their upper part, are invested with a layer of copper, to which is soldered the strip of metal that unites the four carbons of each element to form a single one. This arrangement, which secures a continuity of the contacts, is of a nature to keep the resistance of the pile constant, and, consequently, to contribute to the constancy of the currents.

Although this apparatus has been introduced but a short time, it is being used in some of the hospitals at Lyons, Montpellier, and Brussels, and, if we mistake not, at the Bichat Hospital in Paris.

[It may be remarked that the mechanism for raising and lowering the elements is not wholly new, being nearly if not quite the same as has long been employed by Mr. Drescher, of New York.]

Miscellany.

PHTHISIS AND THE TUBERCLE BACILLUS.—Dr. T. Henry Green (Physician to Charing Cross Hospital, and Senior Assistant Physician to the Hospital for Consumption and Diseases of the Chest, Brompton), in concluding a lecture on the relation of this micro-organism to phthisis, published in the "British Medical Journal," observes, with regard to treatment: What is the practical teaching of Koch's discovery with reference to the prevention and cure of phthisis? If our pathological conclusions be even only partially true, they clearly indicate, I think, the necessity of carefully distinguishing between the bacillus and the conditions which favor its influence, and of directing our treatment to both. We must endeavor to prevent the access of the organism, and, if possible, to destroy it after it has effected an entrance, and we must also strive to maintain a healthy condition of the pulmonary tissues, and thus prevent the occurrence of that tendency to apical stagnation which appears to be such an important, if not essential, factor in the disease. The latter of these indications is, I believe, as important as the former; and it is, perhaps, rather in danger of being lost sight of in the very natural eagerness with which attention is now being directed toward the bacillus.

"Firstly, then, with regard to the condition of the lung which favors the influence of the bacillus. Here it is only necessary to remark that whatever promotes a vigorous state of health will, by improving the condition of the blood, the nutrition of the vessels and activity of the circulation, and the exercise of the respiratory function, tend to prevent that stagnation and transudation in the highest portions of the lungs, the etiological importance of which we have so especially insisted upon. The value of treatment which has for its object the ful-

fillment of these indications in the prevention of phthisis it is, I believe, difficult to over-estimate; and its usefulness is almost equally valuable when the disease is established. I can not but think that, in the mean time, such treatment promises better results than any attempts to attack the specific organisms. Secondly, the tubercle bacillus. The consideration of this naturally divides itself under two heads: (a) the prevention of its access, and (b) attempts to destroy it when the disease is developed. (a) The prevention of the access of the bacillus. The present position of our knowledge appears to point to the desirability of adopting measures for the disinfection and destruction of the sputa of patients suffering from phthisis; and perhaps, also, of the alvine secretions, when there is any evidence of tuberculous disease of the bowel. It also raises the question as to how far it is desirable to allow individuals who are not consumptive, but who inherit a phthisical tendency, and especially when such individuals are out of health, to intimately associate with those who are suffering from the disease. If our pathology continues to move on the same lines, this subject may become one requiring the consideration of those who manage our hospitals. (b) The destruction of the bacillus after the disease is established. Attempts to do this are made principally by means of antiseptic inhalations. This is the fashionable, though perhaps somewhat misdirected, therapeutics of the day. A respirator charged with some antiseptic, such as creasote or carbolic acid, is now being largely used in the treatment of phthisis. Although I should be very sorry to unfairly criticise such treatment, I can not but think that the evidence that its usefulness is in any way dependent upon its destruction of the bacilli, or of any infective substance which they may originate, is wanting. It seems to me much more probable that such inhalations, when beneficial, are so mainly through the favorable influence which they exercise upon the mucous membrane and secretion; and when, as is so often the case, they are combined with chloroform, they will also act as direct sedatives. What we want are cases of early and progressive phthisis in which antiseptic treatment alone, without adjuncts, is followed by marked improvement. When it can be shown, e. g., that the pyrexia of early phthisis is reduced by such treatment, we shall have evidence of considerable value pointing to the influence of the germicides upon the bacillus. We are now making some observations in this direction, but, at present, with negative results. While, therefore, I do not wish to be understood to discourage the treatment of phthisis by antiseptic inhalations, I think we must be careful as to the interpretation we put on their results. The treatment of phthisis and of other pulmonary diseases by means of medicated atmosphere has been greatly stimulated by Koch's discovery. Such treatment has undoubtedly been too much neglected in the past, and its prosecution promises the best results. But, in the mean time, I think we have no evidence that we are able by such means to influence the tubercle bacillus; although, if Koch's investigations be true, the discovery of some agent which, by destroying it, will arrest its injurious influence, is obviously the greatest desideratum."

CEREBRAL DYSPEPSIA.—In the "British Medical Journal," Dr. John S. Main strongly insists on the purely cerebral origin of many forms of dyspepsia, where the patient is neither over-indulgent, nor intemperate, nor addicted to hurrying over meals, nor accustomed to eat coarse or unwholesome food. The cerebral form of dyspepsia is well seen, in many cases, where a healthy man, with a good appetite, suddenly receives bad news when sitting down to a meal. "But, perhaps, of all conditions acting on the brain in this manner, and through the brain on the stomach, no one is more injurious, or more jarring to the cerebral elements, than uncertainty, and the worry caused by the same, more particularly in preternaturally irritable subjects. In fact, it is in connection with this same worry that the form of dyspepsia I have at present under consideration most frequently occurs. The mind in such cases preys upon itself; the cerebral elements seem to get jarred and out of gear: and with this condition the stomach sympathizes. But, in addition to worry, the habitual practice of calling into action the 'reserve fund' of the cerebrum, as already mentioned, will bring about the same consequences—namely, cerebral fatigue and exhaustion, indicated chiefly by preternatural irritability, this condition, sooner or later, telling upon the digestive organs. Having said this, it

is almost unnecessary to add that such cases are most commonly met with among those who are engaged in the hottest part of the 'battle of life,' or 'struggle for existence'; and, again, among these, chiefly those whose business or profession leads to much anxiety, uncertainty, or over-stretching of the mental powers. In over-aspiring, over-ambitious natures 'hope deferred' may bring about the same results; as, according to the biblical expression, 'it maketh the heart sick.' My attention was drawn to several cases of dyspepsia, connected with one or other of these conditions, some time ago; and what made me more strong in my view of these cases being cerebral, and not stomacic at all in their origin, was their obstinacy under all forms of natural treatment. Latterly I have found that the only treatment capable of doing these cases any permanent good is a change, in the wide sense of the term—a relaxation from business or study; and as regards medicines, not such as are meant to act on the stomach directly, but those meant to act on the cerebrum. Among these I have found the most useful to be the bromide of ammonium, or bromide of potassium—preferably the former—given in a sufficient dose at bed-time to secure a good night's sleep, this being often very indifferent, and so tending to complicate the case; and, combined with this, to be taken three or four times during the day, such medicines as are known to have a building-up effect on the nervous system. Among these, the most useful being phosphorus, or the hypophosphites, and cod-liver oil. Arsenic and quinine are often also useful, and a generous diet is always indicated. Unless the stomach has passed into a state of disease (which it may do, if overtasked when in this weakened state), any of these medicines are generally well borne. It will be well to bear in mind, however, that, if the mucous membrane of the stomach be in a state of irritation, quinine, arsenic, phosphorus, the hypophosphites, and sometimes even cod-liver oil, are generally inadmissible."

A JUDGMENT AGAINST THE UNITED STATES MEDICAL COLLEGE.—New York Supreme Court. Special Term. The People of the State of New York, Plaintiffs, against Robert A. Gunn, Benjamin J. Stow, Paul W. Allen, Alexander Wilder, Thomas A. Granger, Mark Nivison, and Dennis E. Smith, Defendants. Judgment, April 4, 1883.

This action having been brought to trial upon the issue of law raised by the plaintiffs' demurrer to the defendants' second defense contained in their answer herein, and beginning with the words, "Second, And for a further and separate defense," and ending at the demand for judgment: and the said demurrer having been, by order of February 5, 1883 (settled and filed March 12, 1883), sustained, with leave to defendants to answer over on payment of costs: and the costs having been taxed at \$108.13: and the order having provided further that unless the defendants pay said costs and amend their answer within twenty days, plaintiffs should have judgment absolute against defendants as for want of an answer: and the defendants having failed to pay said costs, or amend said answer, within the time aforesaid,

Now, on motion of Leslie W. Russell, Attorney-General, attorney for the plaintiffs, it is

Adjudged: That the said defendants are not and have not been incorporated as a medical college, with the franchises or powers of a medical college: and that the said United States Medical College, mentioned in the complaint, is not and never has been incorporated as a medical or surgical college, and does not possess the powers or franchises of a medical college:

And it is further Adjudged: That the defendants, and each of them and all persons acting with or under them or any of them, be and they hereby are enjoined and restrained from acting, or assuming to act, as an incorporated medical or surgical college, and from usurping, or exercising the power, functions, or franchises of an incorporated medical or surgical college: and from maintaining or assuming to maintain, for gain or otherwise, a medical or surgical college: and from granting diplomas or certificates of graduation to medical students or practitioners, purporting to be granted by a medical or surgical college: and that the plaintiffs, The People of the State of New York, recover of the defendants, Robert A. Gunn, Benjamin J. Stow, Paul W. Allen, Alexander Wilder, Thomas A. Granger, Mark Nivison, and Dennis E. Smith, the sum of One Hundred and Eight and 1/4 Dollars, costs and dis-

burements taxed as aforesaid: and that plaintiffs have execution therefor.

(Endorsed, Filed April 4, 1883.)

A copy.

The first practical result of this judgment is realized in the action of the Board of Health of this city, announcing that death certificates signed by graduates of this so-called college will not be recognized. Deaths so certified will be turned over to the coroners for investigation.

NEW ETHICAL ORGANIZATIONS.—The following gentlemen have agreed to form an association to uphold the national code of medical ethics, and to resist any modification of this code that does not emanate from the body in which it originated: John G. Adams, James Anderson, James H. Anderson, William B. Anderton, E. V. Agramoto, S. Busby Allen, Ygnacio Alvarado, Aug. A. Arango, E. A. Arnold, E. S. F. Arnold, Glover C. Arnold, S. S. Bancker, James L. Banks, Wooster Beach, C. M. Bell, E. W. Bennett, Edward J. Bermingham, William N. Blakeman, Nathan Bozeman, Charles K. Briddon, Daniel Brown, L. L. Bradshaw, J. H. Branth, M. Walter Brooks, Joseph D. Bryant, Thomas H. Burchard, E. W. Burnett, Frederick A. Burrall, John Burke, Charles W. Büchler, Aug. F. Büchler, Charles S. Bull, W. T. Bull, Francis D. Buck, Martin Burke, E. M. Cameron, R. A. Caldwell, G. Campbell, Josiah F. Cadmus, James S. Carradine, David C. Carr, Alonzo Clark, Clement Cleveland, Porter F. Chambers, Robert F. Chapman, Jean F. Chauveau, Thos. C. Chalmers, T. M. Cheesman, Thomas F. Cock, William S. Conover, Henry C. Cooper, Stacy B. Collins, David C. Cocks, David C. Comstock, Garrett Cosine, George H. Combs, Charles E. Cross, Joseph S. Crane, P. W. Cremin, H. Holbrook Curtis, John C. Dalton, Samuel W. Dana, Francis De lafield, D. Bryson Delavan, Frederick S. Dennis, Ellery Denison, Richard H. Derby, Wm. Detmold, Edward M. Donlin, A. H. Doty, Abram Du bois, M. B. Du Bois, Coert Du Bois, Milo M. Duntion, John Dwyer, R. Eichler, C. Ruxton Ellison, J. O. Farrington, J. E. Ferdinand, M. D. Field, Thos. C. Finnell, Austin Flint, Austin Flint, Jr., M. J. Fleming, Jas. W. Flynn, Percival H. Flynn, Joel Foster, George C. Freeborn, J. Gordon Frazer, David Franklin, J. P. Garrish, T. T. Gault, J. W. S. Gouley, O. A. Gorton, Horatio Gomez, Gaspar Griswold, Frank H. Hamilton, Edwards Hall, Samuel Hall, W. H. Hall, W. L. Harding, Geo. T. Harrison, S. D. Harrison, J. J. Henna, Geo. A. Hershell, A. J. Henriques, S. Audgen Hill, Chas. Hitchcock, John H. Linton, George B. Hitek, Abbott Hodgman, Samuel T. Hubbard, Francis Huber, F. Justace, J. B. Hunter, Joseph J. Hull, John B. Isham, W. H. Jackson, E. G. Janeway, J. C. Jay, Jr., J. E. Janvrin, S. Beach Jones, W. W. Jones, Adolph Kessler, T. Kenneth, B. M. Kerney, J. B. Lawrence, Chas. Laight, J. R. Leaming, Chas. A. Leale, Arthur J. Leary, Noah C. Levings, R. P. Lincoln, B. A. Lindsay, Jared Linsly, Wm. T. Lusk, P. J. Lynch, Arch. Lybold, J. F. Lyon, Francis Markoe, Thomas M. Markoe, Thos. H. Manley, David Magic, W. S. Mayo, Chas. McBurney, B. W. McCready, Jas. W. McLane, Calvin B. McQuesten, T. S. P. Miller, R. L. Miranda, J. L. Minor, H. W. Mitchell, Joseph A. Monnell, G. H. Müller, Jr., Robert S. Morris, Wm. J. Morton, Bowditch Morton, A. B. Mott, Valentine Mott, S. S. Mulford, Chas. E. Nelson, Robert Newman, Henry D. Nicoll, Henry D. Noyes, T. F. O'Brien, R. J. O'Connell, William O'Donnell, Joseph O'Dwyer, Samuel H. Orton, Willard Parker, Willard Parker, Jr., E. H. Peaslee, Geo. L. Peabody, Henry T. Pierce, P. B. Porter, Samuel S. Purple, John Purcell, Henry F. Quackenbos, John J. Reid, Ira B. Read, Pio Renfio, Chas. F. Roberts, Thomas S. Robertson, Alvah Rowe, Lewis A. Sayre, Lewis Hall Sayre, J. Stanford Sayre, G. A. Sabine, T. T. Sabine, George Scott, W. D. Schuyler, Frederick S. Sellow, Henry Sheppard, John Shraday, Lewis Shuitze, Chas. E. Simmons, O. G. Smith, Stephen Smith, J. Lewis Smith, James O. Smith, Chas. D. Smith, Hanbury Smith, F. P. Stevens, Isaac E. Taylor, James R. Taylor, Robert Taylor, J. A. Ten Eyck, Seligman Teller, T. Gaillard Thomas, J. Tomlinson, John G. Truax, Carlos T. Tucker, M. E. Tully, Marcus C. Tully, E. G. Tuffs, Wm. A. Valentine, Henry Van Arsdale, M. D. Van Pelt, Edward H. Van Winkle, E. B. Warner, Charles S. Ward, John W. Warner, Robert Watts, J. G. Wallach, J. A. Walther, F. D. Weisse, W. H. Welch, H. G. Wetmore, O. P. Wells, J. Wiener, William T. White, Octavius A. White, Francis V. White, J. Blake

White, Charles S. Wood, J. W. Wright, Charles Wright, Leroy M. Yalc, William Young.

In accordance with a call signed by Alfred C. Post, C. R. Agnew, Fordyce Barker, W. H. Draper, F. N. Ovis, H. B. Sands, S. O. Vanderpool, Robert F. Weir, A. Jacobi, A. E. M. Purdy, Thos. Addis Emmet, and Alfred L. Loomis, a large meeting was held at the house of Dr. A. Jacobi, on Friday evening, the 6th inst., at which many representative men from various parts of the State were present, Dr. Alfred C. Post in the chair. A committee of fifteen was appointed to report a plan for the organization of an association to oppose the re-enactment of the code of ethics of the American Medical Association by the Medical Society of the State of New York.

The following-named gentlemen were appointed on the committee, with power to fill vacancies, and to add to their number: W. W. Potter, of Buffalo; J. D. Spencer, of Watertown; W. C. Wey, of Elmira; B. F. Sherman, of Ogdensburg; W. H. Bailey, of Albany; W. S. Ely, of Rochester; Edwin Hutchinson, of Utica; H. B. Sands, J. L. Little, A. L. Loomis, F. Barker, A. H. Smith, and R. F. Weir, of New York; J. S. Prout and L. S. Pilcher, of Brooklyn. To these were added *ex-officio* the President of the meeting, Dr. A. C. Post, and the Secretary, Dr. F. R. Sturgis.

AN APPEAL FOR THE OLD CODE.—We have been requested to publish the following:

To the Members of the Regular Medical Profession in the State of New York.

GENTLEMEN: Representing a large number of physicians associated to uphold the National Code of Medical Ethics, we beg leave to ask you to consider the importance of the object.

The so-called new code recently adopted by the Medical Society of the State of New York sanctions fellowship by means of consultations with all practitioners who are "legally authorized to practice medicine." This sanction extends to practitioners who have adopted designations intended to distinguish them as belonging to sects apart from, and hostile to, the regular medical profession, and who are organized in order to lessen public respect for this profession and for its members. Will you not seriously consider the question whether, under these circumstances, affiliation by any act with sectarian or irregular practitioners is consistent with a due regard for the honor of the profession, or with a proper sense of self-respect?

The new code has dissevered all connection by representation, of the Medical Society of the State of New York and its auxiliary county medical societies, with the American Medical Association, and, also, with the State medical societies of the several States of the Union. At the last meeting of the American Medical Association (1882) the Judicial Council decided as follows: "Having carefully examined the Code of Ethics adopted by the New York State Medical Society at its annual meeting in February, 1882 (as furnished by the secretary of said society), the Judicial Council find in the said code provisions essentially different from, and in conflict with, the Code of Ethics of this association; and, therefore, in accordance with the provisions of the Ninth By-Law of the American Medical Association, they unanimously decide that said New York State Medical Society is not entitled to representation by delegates in this association. The following is the by-law referred to in the foregoing decision: "No State or local medical society, or other organized institution, shall be entitled to representation in this association that has not adopted the Code of Ethics, or that has intentionally violated or disregarded any article or clause of the same."

We submit for your consideration that the substitution of the new code for that adopted by the American Medical Association has inflicted upon the medical profession of this State a great injury and disgrace.

It is believed that the recent action of the New York State Medical Society in relation to the Code of Ethics is not sustained by the sentiments and judgment of the great majority of the medical profession in the State. But, even granting that they who are opposed to this action are in the minority, it must be admitted that the number is very large. The effect of the action of the State society, if persisted in, will be a division of the profession of the State into two parties. In view of the evils which can not but follow such a division, and the

many advantages of harmony, we appeal most earnestly to those who have been led to approve of the substitution of the new code for that of the national to reconsider the matter, and we solicit the active co-operation of all who are in favor of the national code, in concerted efforts to effect, as speedily as possible, a reversal of the action of the Medical Society of the State of New York at the annual meetings in 1882 and 1883.

Communications from societies and individuals who are in sympathy with associations for upholding the National Code of Medical Ethics, and resisting any modification of that code which does not emanate from the American Medical Association, may be addressed to JOHN H. HINTON, M. D., No. 41 West Thirty-Second Street, New York City.

RESIGNATION OF PROFESSOR DETMOLD.—At the close of a recent clinic of his regular Wednesday course at the College of Physicians and Surgeons, Professor William Detmold announced to the class that he had now relinquished his position at the college. He is reported to have used these words: "When in my younger days I began the practice of medicine, in Northern Germany, the fee allowed us by law for a visit was eighteen cents. Many were unable to pay so much. On my entering upon practice in New York, now over forty years since, I was called upon by many poor persons for treatment—persons who were unable to pay. I allotted a certain hour in each week for their special treatment. The number of such patients became very great. Students from every quarter of the city visited my office at these private clinics. For five years I continued in this way, at the end of which time a committee from this college waited upon me and requested me to transfer my clinic to this school, to which proposition I assented. That was the origin of this clinic, which has now been held for so many years. Now I am going to quit."

The clinic will be continued by Dr. Robert F. Weir.

THE DISLIKE OF DOCTORS.—Lady Florence Dixie assigns as a reason for her refusal to send for a medical man to see her after the recent attack made upon her, "I dislike doctors!" It would have been, in many ways, wise to call in the assistance of a trusted practitioner after such injuries as her ladyship is alleged to have received. We are not, however, interested in that matter so much as in the fact that there is such a feeling as "dislike of doctors." In part, doubtless, this feeling may arise from the recognition that "doctors" stand very much in the same relation to the body and mind as the minister of religion occupies toward the conscience. A medical man lifts up the veil and sees the psycho-physical being behind it. Probably in a certain proportion of instances the sense of being known is not pleasant. The feeling that a fellow-mortal possesses a deep insight into the actual condition of the organism, and is able to form a clear and approximately full and accurate estimate of the character, may, in some instances, be disquieting, while in others it engenders that sort of self-consciousness on the part of the patient which is experienced by devout penitents in the presence of their confessors, a feeling of mingled trust and anxiety, of satisfaction and regret. We can not believe that any other form of "dislike of doctors" than that many-phased feeling to which we have alluded can prevail. The medical adviser is, or ought to be, the best known and the most sincerely trusted of all the friends of his patient. His friendship should be even more thoroughly a sentiment of the inner life than any other. It is in this light the lay public should view their family doctors, and in this esteem the practitioner should aim to be held.—*Lancet*.

SEWER GAS IN PHILADELPHIA.—At a meeting of citizens, held last week in Philadelphia, to consider measures for the more effectual prevention of the injurious effects of sewer gas, the inactivity of the Board of Health was commented on, and the following gentlemen were appointed a committee to prepare a plan of action: Mr. Jonas Langfolt, Dr. W. B. Atkinson, Dr. Benjamin Lee, Mr. David Evans, Mr. L. O.

Howell, Jr., Mr. O. B. Evans, Dr. W. R. D. Blackwood, and Dr. C. C., Vanderbeck.

THE LATE SURGEON-GENERAL BARNES.—Not only among the profession in America, but in every country which recognizes the splendid services rendered to military medicine by the medical corps of our army during the past twenty years or more—services with which General Barnes is everywhere known to have been conspicuously associated for the greater portion of that period—the news of his death will fall as a blow, tempered only by the reflection that his active career had already drawn to a close on the addition of his name to the retired list, and by the trust, for which there is such ample foundation, that the management of the Surgeon-General's office is still in most competent hands.

Brigadier-General Joseph K. Barnes died in Washington on the 5th inst., of Bright's disease, in the sixty-sixth year of his age, having been over forty years in the army. He was born in Philadelphia, July 21, 1817. In 1838 he received the degree of doctor in medicine from the Medical Department of the University of Pennsylvania. After serving for several months in the Blockley Hospital, as a member of the house staff and in the out-patient department, he joined the medical corps of the army, receiving his appointment as Assistant Surgeon June 15, 1840. Having served at the Military Academy, in the Florida War, in the Mexican War, and again at West Point, he was appointed Surgeon August 29, 1856. At the outbreak of the late Civil War he was recalled to Washington from a post on the Pacific coast, and was made Medical Inspector with the rank of Lieutenant-Colonel February 9, 1863. On the 10th of August of the same year he was made Inspector-General with the rank of Colonel. The following year, on August 22d, he was appointed Surgeon-General with the rank of Brigadier-General. In 1865, at the close of the war, he was breveted Major-General, and last year he was retired in compliance with the general law.

In a general order, Adjutant-General Drum says of General Barnes: "He was eminent, skillful, and successful in his profession as surgeon and physician, and distinguished for great administrative ability as the head of the medical department. He inaugurated the 'Medical History of the War,' he founded the Medical Museum, and he brought the medical department to the highest state of efficiency. During the troublous times of the late war he earned the unbounded confidence of the Secretary of War, Mr. Stanton, and held it unshaken to the last. At the time of the assassination of President Lincoln and the attempted assassination of Secretary Seward, he attended at the deathbed of the one, and ministered with untiring energy and skill to the successful restoration of the other. So, during the long illness of President Garfield, he was one of the distinguished surgeons of the land who for days and nights served with devoted duty in the sick chamber of the dying President. During these long, protracted hours of anxiety and care his own health gave way, and from that moment to the time of his death he was an invalid. His career was one of honor to himself and of great service to his country."

DEATH OF PROFESSOR VON BRUNS.—This distinguished German surgeon, Director of the Department of Clinical Surgery at the University of Tübingen, has recently died at that town. He was a native of Brunswick, where he was born in 1812. He is chiefly known to the profession for the prominent part he has played in connection with the surgery of diseases of the larynx and the use of the laryngoscope. He contributed to medical literature a text-book on surgery, several papers and pamphlets on nasal polypus, and a valuable work on laryngoscopy, embellished by an atlas. His health had been failing for some time before his death, ever since an attack of apoplexy in the autumn of 1881, which led to his retirement from the professorship of surgery in the University.—*British Medical Journal*.

DEATH OF PROFESSOR ROSSO.—Professor Giuseppe Rosso, of the University of Genoa, died recently in that city. He had held the position of Professor of Surgery since 1851.

DEATH OF M. LASÈQUE.—Professor Charles Ernest Lasèque, physician to the Paris hospitals, and for the past ten years one of the editors of the "Archives générales de médecine," to which journal he

contributed many notable articles, died on the 20th of March, in his sixty-seventh year.

THE SKIN AND CANCER HOSPITAL.—It is announced that an entertainment will be given at Delmonico's on the afternoon and evening of the 24th inst., in aid of the new Skin and Cancer Hospital. It is said that the entertainment, termed a "kirmess," is to present some features of novelty, being in imitation of the old Dutch spring-tide festivals. The affair will be under the direction of the Ladies' Auxiliary Board of the hospital, comprising Mrs. John A. Lowrey, Mrs. H. A. V. Post, Mrs. E. C. Hall, Mrs. L. D. Bulkeley, Mrs. B. H. Van Auker, Mrs. F. T. Woodbury, Mrs. W. C. Dewey, Mrs. D. T. Worden, Mrs. G. H. Fox, Mrs. Richard Irvin, Jr., Mrs. James B. Hunter, Mrs. Julius Craft, Mrs. J. C. O'Connor, Mrs. Julius Catlin, Jr., Miss Mary L. Walker, Miss Olivia Stokes, Mrs. John D. Prince, Mrs. D. M. Porter, Mrs. W. L. Schermerhorn, and Mrs. R. H. Lounsbery.

WINTER CHOLERA IN NEW ENGLAND.—In a recent report of the Connecticut State Board of Health, prepared by Dr. C. W. Chamberlain, of Hartford, to whom we are indebted for an advance proof, we find the following: "There has been a peculiar type of disease in the State, which, as far as I can learn, appeared for the first time in New England this winter. I refer to what is called winter cholera. It was prevalent in Providence, R. I., and followed shortly after in Waterbury. Last year there were accounts of it in certain western cities. It appears in an epidemic form. No local cause has yet been found to be even usually associated with it. The disease is wrongly called cholera, for it does not produce death directly, and very rarely, if ever, indirectly. The symptoms are profuse watery discharges which evidently come from the blood, severe cramps, a pinched, sunken countenance—that is, the eyes appear sunken. After it is well established there is a cold stage, the temperature falling to 97 degrees, and cases are reported as low as 96 degrees. . . . The average duration is four days. The symptoms somewhat resemble those of cholera, hence the name. Thus far cities only have been attacked. I have learned of no genuine cases originating in the country. In most places the cases have been mainly among the prosperous, well-to-do citizens. In only one epidemic have I learned that a cause was assigned that was at all probable. There the poor living in tenement houses only were seized, and succine, or rather lard butter, which was poorly prepared, was charged as the cause, but this appears hardly probable, as no such association has been since found to exist. It is a peculiar disease, but easily controlled by treatment. A few cases similar to the winter cholera are reported from Cheshire."

THE EDINBURGH ROYAL INFIRMARY.—The "Medical Times and Gazette" states that Dr. P. MacBride, Surgeon to the Edinburgh Ear Dispensary, and Lecturer on Diseases of the Ear in the Edinburgh School of Medicine, has been appointed to the post of Aurist and Laryngologist to the Royal Infirmary.

A NEW OBSTETRIC PHYSICIAN TO GUY'S HOSPITAL, LONDON.—The "Medical Times and Gazette" understands that the vacancy caused by the resignation of Dr. Braxton Hicks, Obstetric Physician to Guy's Hospital, has been filled by the appointment of Dr. Galabin, who is to be succeeded as Assistant Obstetric Physician by Dr. Horrocks.

THE TEXAS STATE MEDICAL SOCIETY.—The annual meeting of the society will be held at Tyler, on the 24th inst.

THE CROTON WATER.—The people of New York have seldom had reason to complain of the quality of their drinking-water; the general conviction is that it is good, what there is of it. It is reassuring, however, to have this impression confirmed by chemical examination, and to be able to record, on the authority of Professor Leeds, of the Stevens Institute, that the nitrate-of-silver actinic test produces comparatively little coloration of the Croton water, decidedly less than of some of the rural streams near New York.

JEFFERSON MEDICAL COLLEGE ALUMNI.—According to the "Medical News," the following-named gentlemen were recently elected officers of the Alumni Association of the Jefferson Medical College, of Philadelphia: President, Dr. Samuel D. Gross; Vice-Presidents, Dr. Adinell

Hewson, Dr. R. J. Levis, Dr. Ellwood Wilson, and Dr. W. W. Keen; Recording Secretary, Dr. Thomas H. Andrews; Corresponding Secretary, Dr. R. J. Dauglison; Treasurer, Dr. Nathan Hatfield.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from March 31, 1883, to April 7, 1883.*—HAMMOND, JOHN F., Colonel and Surgeon. Granted leave of absence for six months on surgeon's certificate of disability, with permission to go beyond sea. Par. 6, S. O. 75, A. G. O., April 2, 1883. — HAMMOND, JOHN F., Colonel and Surgeon. To be relieved from duty in the Department of the East, and to report by letter to the Surgeon-General, U. S. Army. Par. 7, S. O. 75, A. G. O., April 2, 1883.

NAVAL INTELLIGENCE.—Surgeon John H. Clark and Passed Assistant Surgeon P. A. Lovering have been ordered to the Lackawanna, of the Pacific squadron, taking passage from New York on the steam ship sailing April 20th. — Passed Assistant Surgeon Robert Whiting has been ordered to the receiving ship Wabash. — Surgeon Charles H. White and Passed Assistant Surgeon A. C. Heffenger have been detached from the Lackawanna, and ordered to return home on the reporting of their relief, and report their arrival. — Surgeon J. H. Kidder has been detached from the Albatross, and granted leave of absence for three months. — Passed Assistant Surgeon C. G. Herndorn has been detached from the receiving ship Wabash, and ordered to the Fish Commission steamer Wabash. — Assistant Surgeon Joaquin D. Castillo has resigned, to take effect October 3, 1883, and has been granted leave until that date. — Medical Director J. J. Turner has been elected Second Vice-President of the Navy Mutual Aid Association, and Medical Inspector S. Kindleberger and Passed Assistant Surgeon P. M. Rixey have been elected resident directors. — Medical Director F. M. Gunnell and Medical Inspector David Kindleberger are on the Retiring Board now in session at Washington. — For the foregoing items we are indebted to the "Army and Navy Journal."

MARINE HOSPITAL SERVICE.—*Official List of Changes of Stations and Duties of Medical Officers of the United States Marine-Hospital Service, January 1 to March 31, 1883.*—BAILLACHE, P. H., Surgeon. Detailed as member of board for the examination of officers of the Revenue Marine Service, March 27, 1883. — MURRAY, R. D., Surgeon. To proceed to Vicksburg, Miss., as inspector, March 24, 1883. — PURVIANCE, GEORGE, Surgeon. To proceed to Cleveland, Ohio, to investigate management of hospital, January 22, 1883. Granted leave of absence for seven days, February 8, 1883. — AUSTIN, H. W., Surgeon. To proceed to Gallipolis, Ohio, as inspector, January 9, 1883. — FISHER, J. C., Passed Assistant Surgeon. Detailed as member of board for the examination of officers of the Revenue Marine Service, March 27, 1883. — CARTER, H. R., Passed Assistant Surgeon. To proceed to New Orleans, La., for temporary duty. Thence to San Francisco, Cal., for duty, February 7, 1883. — PORTER, F. D., Passed Assistant Surgeon. Granted leave of absence for thirty days, February 10, 1883. — GUTERAS, JOHN, Assistant Surgeon. Granted leave of absence for thirty days, January 19, 1883. — WHEELER, W. A., Assistant Surgeon. To proceed to Chicago, Ill., for duty, January 27, 1883. — ARMSTRONG, S. T., Assistant Surgeon. To proceed to Key West, Fla., for temporary duty, February 1, 1883. — BENNETT, P. H., Assistant Surgeon. To proceed to Charleston, S. C., for temporary duty, February 19, 1883. — PORTER, F. D., Passed Assistant Surgeon. Resignation accepted, to take effect March 31, 1883.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Tuesday, April 17th:* Academy of Medicine (Section in Practice); Obstetrical Society (private); Medical Society of the County of Kings (Brooklyn). *Wednesday, April 18th:* Comitia Minora of the Medical Society of the County of New York; New Jersey Academy of Medicine (Newark). *Thursday, April 19th:* New York Academy of Medicine.

ERRATUM.—In Dr. Piffard's article, in this number of the journal, p. 401, second column, twenty-first line, for "Dr. J. G. Adams" read *Dr. White*.

Original Communications.

THE NECESSITY FOR A CODE OF MEDICAL ETHICS.

By D. B. ST. JOHN ROOSA, M. D.

THE letters of Dr. Flint and Dr. Barker which have lately appeared in the "New York Medical Journal," the series of articles by Dr. Flint, and the paper by Dr. Hopkins, as well as the editorial comments upon them, seem to invite those who have mentally formulated their views upon the subject of codes of ethics to publicly express them. I am personally very glad of the opportunity to speak upon a subject in regard to which my views, in certain circles, seem to have been misunderstood, in a place free from the excitements of a meeting of the profession, where votes are taken and counted. To those who are not delegates to or permanent members of the New York State Medical Society, a few words in the way of history are necessary, in order that the resolutions offered in 1882, and which by Dr. Elsborg are considered as worthy to be entitled the "Gentleman's Code," may be fully understood. Those resolutions read as follows:

"The Medical Society of the State of New York, in view of the apparent sentiment of the profession connected with it, hereby adopt the following declaration to take the place of the formal code of ethics, which has up to this time been the standard of the profession of the State:

"With no idea of lowering in any manner the standard of right and honor in the relation of physician to the public and to each other, but, on the contrary, in the belief that a larger amount of discretion and liberty in individual action, and the abolition of detailed and specific rules, will elevate the ethics of the profession, the medical profession of the State of New York, as here represented, hereby resolve and declare that the only ethical offenses for which they claim and promise to exercise the right of discipline are those comprehended under the commission of acts unworthy a physician and a gentleman.

"Resolved, Also, that we enjoin the county societies and other organizations in affiliation with us, that they strictly enforce the requirements of this code."

There was no caucussing of any kind, either with the members of the Committee on Ethics, whose duty it was to present a revised code, or with other members of the society, when this was introduced, or previous to its introduction. It was a great surprise to Dr. Wey, Dr. Van der Poel, Dr. Agnew, and Dr. Piffard when I presented it. Dr. W. S. Ely, the last named on the committee, knew of it, and he almost by accident. He had read it carefully. I have reason to believe that the committee on the new code would have presented their report in a very different way had they anticipated that any considerable number of the State society, much less a majority of those present, were anxious to go further than they in simplifying the code. As it was, their report was presented with the idea that it would be criticised line by line, and section by section. But, when the foregoing resolution was offered at a large meeting of the society, assembled with a full knowledge that a revised code was to be presented—a meeting composed of delegates

and members from all parts of the State—the debate took a different turn from what was thought possible by the committee, and turned, not on the necessity for a revision of the code, but on the point as to whether a detailed code was at all necessary. In that debate, extemporaneous and vigorous, there were but two speakers who made any argument for the old code, and, on an analysis of the vote, it will be found that not more than twelve or fourteen of the seventy-eight votes cast were in favor of it.

When it was found that my resolutions had failed from want of the constitutional two-thirds vote, after some conference, the friends of the declaratory resolution and of the new code united in voting for the report of the committee, and thus secured its passage. The hour was so late that there was no time for any discussion of the committee's report, or, it is confidently believed by many, it would have undergone revision in many respects. After the meeting was over and discussion became general by the press of the whole country, especially and only on the consultation clause of the new code, it was evident that the old code would again be incorporated in the by-laws of the society unless there was a thorough union of all those opposed to it. Such a result would have been equally obnoxious to those who supported the committee's report, and to the friends of the declaratory resolutions. A union therefore occurred, and the contest in Albany became virtually narrowed down to this: "Shall the members of the New York State Medical Society be allowed to continue in the freedom of consultations given them by the new code, or shall this be taken away from them because the American Medical Association refuses its assent to such a liberty?" The two thirds who voted for the new code were told by one speaker, in the debate that preceded its passage, that they must inevitably cut themselves off from this association by their action; but they were not awed by the statement. It is my belief that each member of the profession has an inherent right to give his professional advice whenever he may choose, and that he may not be compelled to give it unless he does choose to. I do not think, moreover, that the American Medical Association will formally admit this right within a reasonable future, and I therefore, with many others, prefer to support a code that accords this right rather than one that expressly denies it, even if by such a support we seem to yield the principle we hold dear, that a profession needs no code other than the common law of the land. But, now that the field is clear of side issues for a time, the friends of the declaratory resolutions are very glad of an opportunity, free from an entangling alliance with the friends of the new code, pure and simple, to express their views on the question involved. We regard the old code, except as to the consultation clause, as chiefly a hand-book of etiquette. Proof that this is a correct view may be found by reference to the sections which state that the mind of the physician "ought to be imbued with the greatness of his mission." "They should study in their department so to unite tenderness with firmness, condescension with authority, as to inspire the minds of their patients with gratitude, respect, and confidence."

"A patient should never weary his physician with a tedious detail of events and matters not appertaining to his disease." Now, all these things are true enough, but they are matters pertaining to manners and not to morals. If they and scores of others like them are not taught by parents teachers, by the ordinary intercourse of society, they can never be learned at all. Polite society has long since discarded books of etiquette; not that etiquette is not important and even necessary, but we do not believe that it can be taught by hand-books. Only the vulgar and ignorant resort to them.

One of the funniest scenes in "She Stoops to Conquer" is the attempt of Squire Hardcastle to drill his motley servants, headed by Diggory, into well-trained waiters, in the few hours before the arrival of London guests. An attempt to make cultivated gentlemen by the proper rules of a code of ethics will be a failure as great as that of the Squire's over Diggory's hands and knees. There is not a line of these directions regarding the etiquette of medical men that is not self-evident to any properly educated medical practitioner as a proper course of conduct. As to the value of a code for our patients, it is probable that well-bred people will always treat us as well as we deserve, and ill-bred one will always continue to annoy us, in spite of a code which tells them that they ought not to. It seems, to those of us who consider the greater part of the code as a mere hands book of etiquette, that Dr. Flint, in his commentaries now being published in your journal, is only undertaking a work of supererogation in discussing the self-evident truths of many parts of the code. What shall we think of a man who, having entered the medical profession, needs to have a printed formula to tell him that "consultations should be promoted in difficult cases, as they give rise to confidence, energy, and more enlarged views of practice"; or that "the opportunity, which a physician not unfrequently enjoys, of promoting and strengthening the good resolutions of his patients suffering under the consequences of vicious conduct, ought never to be neglected"? A man who has not the wit to get aid from consultations when he is in doubt about a case under his care, or the moral character to counsel a patient suffering the effects of a bad life, will hardly acquire these things from a written code. Even Dr. Flint, with all his admiration for the code, is constrained to admit that it is indelicate for a member of the profession to dilate largely on the "obligations of patients to their physicians"; and he dismisses the pedantic article devoted to this subject in the code with very little remark. Indeed, the strongest mental digestion would quail at this morsel. The idea that physicians should gravely enjoin their patients to "prefer a physician whose habits of life are regular, and who is not devoted to company, pleasure," etc., is one that would not enter the mind of the average man, or that "a physician should never weary his patient with a tedious detail of events and matters not appertaining to his disease." And do we all agree that "justice and common courtesy require" that a patient should declare his reasons for dismissing his physician? I am not so sure that a physician is anxious to know the reason for his dismissal. He may at least assume that he is not wanted, if he be dis-

missed, without waiting for an elaborate note in which his want of qualifications are set forth. It seems, to those of us who believe that the profession requires no formal code beyond the declaration that a physician must behave like a gentleman, that a hint that our services are no longer required will be quite sufficient when dismissed from a case. We consider such paragraphs, of which I have given specimens, as peurile. Dr. Noyes said, in his speech on the code in 1882, that he well remembered the feeling of surprise that came over him when he first read the Code of Medical Ethics. "It seemed to be saying things that were both humiliating and unnecessary." Dr. Flint's articles will, I think, reawaken these feelings in many minds. We all agree that "it is derogatory to the dignity of the profession to resort to public advertisements or hand-bills, inviting the attention of individuals affected with particular diseases, . . . to boast of cures and remedies," and so forth, but ours is the only profession that does not think it derogatory to its dignity to make laws on such matters. It is the only profession in which the members are not content to leave such plain matters of taste to the good sense of each of its members. There is a Coventry, even in our profession, which furnishes a complete exile for men who would shock good taste by such violations as are implied in this paragraph. But the friends of the old code are like the advocates of sumptuary laws: they believe that all evils may be corrected by rules. I forbear, however, to discuss the code further in detail, but I pass on to the clause which is really at the bottom of all the excitement that has been caused by the action of the Medical Society of the State of New York. The consultation clause is almost the only essential one which the new code abrogates, and this is the one for which our brethren are now struggling. At this point the division between the State of New York and the American Medical Association is marked. Here the new-code supporters and those who advocate a simple declaration, or "a gentleman's code," are agreed. Yet we who argue for a simple declaration would allow even this to be unwritten. Higher than the law which allows a physician to consult with any other "legally qualified practitioner," to our mind, is the law that allows each man in the possession of knowledge to give it freely whenever it is honestly asked. We can not see how discussion is possible over such a self-evident right. All the words about "affiliating with quacks," "degrading the profession," "mercenary motives," which have been so freely used in this debate, can not cover up the main issue. Can a man give his advice whenever in his opinion it will do good? Has he a right to give his professional services whenever they are asked? The issue is not, Shall he be compelled to give them when he is sure they will be as pearls before swine; but, Shall he be cast out from the profession because he honestly gives his advice whenever in his judgment it will do good, even if to homœopaths and eclectics. The men who fear that this liberty will degrade the profession of medicine, and cause its members to fall away into the methods of charlatans, must, indeed, have a low estimate of the intrinsic qualities of medical men that have been trained in the regular schools and societies of America. If freedom in consultations will

cause us to degenerate from the position we have won, if individual freedom to do as we think best in such a matter will degrade us, then let us meet our fate and let a better race of men take our places.

There is no justice in the comparison made by the advocates of codes between laws against crime and rules of etiquette. Even in matters of civil law men are generally agreed that we have too many laws, but those of us who declare a specific code for the medical profession unnecessary also know that the civil law is ample to prevent crime so far as law will do so. We are not willing, however, to admit that advertising skill, holding patent rights of surgical instruments, consultations with men who have not the correct views of therapeutics, are crimes, although some of these acts may be breaches of good taste. There is no justice in any such comparisons.

It certainly is not in good taste for a judge to sit in court with his feet higher than his head, or to hold its sessions while he is in his shirt-sleeves, but these breaches of manners, which sometimes occur in our country, have not yet induced the legal profession to draw up a code of etiquette. The arguments against the old code apply with equal effect to the new, except that very many of the puerilities of the old code are stricken out, so that the code is much shorter. The first section opens with the familiar phrase, "It is derogatory to the dignity," etc., and proceeds to tell us that we shall not violate good taste and resort to public advertisements. It has, however, a remarkable phrase not to be found in the old code. This is the one which says that it is derogatory to the dignity of the profession to allow our opinions on medical and surgical questions to appear in the newspapers. Now, this may be true or it may not. In times of epidemics even the publication of a formula for the relief of cholera morbus would certainly be of value to the profession, as it has been in the past, even if it contain an opinion on a medical subject. While it is, no doubt, a good general rule that the newspaper is not the place for medical and surgical opinions, there are many times when this avenue to information becomes just the means of humanely serving the public. This, as well as the subsequent clause, as regards giving certificates, could safely be left to the good judgment of the profession. After the famous consultation clause of the new code, there are some few rules in regard to the etiquette of consultations that are well enough, but they are open to the same objections that are made to those of the old code. They are unnecessary. The third and final section of the new code is devoted to the relations of physicians to each other. In the first place, the very proper statement is made that "all practitioners of medicine, their wives, and their children while under paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them." This will hardly be disputed, I think, nor will the other clauses in regard to the attendance by a practitioner on a sick brother's patients during his illness. The matter of carrying on medical controversies in newspapers and pamphlets is then discussed, and the New York State code closes.

It is more remarkable, except in the matter of consultations, and interviews with reporters, for what it does not say than for what it does. It is a great improvement upon

the prolix, verbose, and puerile details of the old code, and it will therefore be earnestly supported by many members of the profession, who desire either a simple declaration or no words at all, until the day comes when, as in many older lands, the profession in this country does its work without a book of etiquette, and without any restrictions to prevent an individual member from giving his advice wherever it may do good.

The argument that we should wait for the American Medical Association before we attempted any change in the code of our State would be more weighty with many of us if we had a greater respect for the methods and organization of that association. The chartered representative organization of our State is not to be compared to such a loosely organized body as the so-called American Medical Association. Permanent members of the New York State society are chosen in limited number only, and then from those who have served as delegates for three years. A man who has once been a delegate to the American association becomes a permanent member by subsequent attendance and payment of five dollars per annum. It is in no sense a representative body. It is one that is very easily packed, an impossibility with such a body as that of our State. The meetings of the American association are more or less well attended, according to the city in which it may happen to meet. In this wide country it is practically impossible with such an organization as that of this association to secure a fairly representative assemblage in any city, east or west, north or south. As an association in which the profession from all parts of the country may meet convivially, or socially, or scientifically, it may have a certain value. But, as a body to legislate for the profession of the different States, it certainly has been, and will continue to be, a failure. Certainly the profession of the leading State, as regards medical position, is not prepared to give up its own chartered and time-honored legislative powers to a medical mass-meeting. If we must have a national code of ethics, let us have a proper national body to formulate it. Then, perhaps, the State of New York will yield the rights she now claims to possess, but she is as yet unawed by the clamor of those who are open to the suspicion of being jealous of her fame.

THE QUESTION OF TREPHINING IN INJURIES OF THE HEAD.*

By H. B. SANDS, M. D.

The operation of trephining the skull having been performed in my service at the Roosevelt Hospital in seven cases during the past year, I have thought that a brief account of these cases might be profitable, by eliciting from the members of our society their experience in the operation, and more especially their views in regard to the indications for its performance. For ages past, no surgical procedure has been the subject of keener controversy; and the diversity of opinion which still prevails concerning it suffices to prove that the question of its value is yet unsettled, and that it is one of inherent difficulty and obscurity. Fur-

* Read before the New York Surgical Society, March 27, 1883.

ther discussion, therefore, appears to be desirable; particularly when we consider the fact that a few American surgeons have lately endeavored to extend the sphere of the operation by reviving the obsolete practice of trephining in cases of simple fracture attended with displacement or depression, even in the absence of head symptoms, and merely as a preventive measure.

Before proceeding to relate briefly the cases above referred to, it may be proper to state that I shall employ the term trephining in its wider sense, which includes under this designation the several methods by which fragments of bone are elevated or removed, whether by means of a trephine, Hey's saw, chisel, elevator, or gouge-forceps.

Out of the seven cases, the operation was performed once for simple fracture with depression, four times for compound fracture with depression, and twice for epileptic and paralytic affections following an injury.

CASE I.—On August 23, 1882, a boy, aged thirteen, was brought to the hospital in a semi-comatose state, caused by a fall from a horse just before his admission. On examination, a scalp wound was found over the left, and a hæmatoma over the right parietal bone, but no fracture was discovered. The left side of the body was partially paralyzed.

Treatment.—Iodoform dressing to scalp wound; ice-cap to head.

August 25th.—Patient still comatose. Dr. Halsted, the assistant surgeon, suspecting fracture, made a crucial incision over the right parietal bone, and discovered an extensive depressed fracture of the right temporal and of both parietal bones, running upward beyond the vertex. A large piece of the temporal, and several fragments of the parietal bone were elevated or removed, and, on following up the line of fracture to the vertex, a rent was found in the dura, through which a considerable amount of brain substance had escaped. During the operation, the superior longitudinal sinus was wounded. Bleeding was arrested by pressure, and the external wound was partially closed by suture. Consciousness did not return, and death occurred two hours after the operation.

Evidently, in this case, the operation was useless; and, undoubtedly, it would not have been undertaken if the extent of the injury had been known beforehand. The case may serve, however, to enable us to discuss the general question as to the expediency of trephining in simple depressed or comminuted fracture, accompanied or not by symptoms of compression or other cerebral injury. It is hardly necessary to remark that a fracture of the skull derives its chief importance from the concomitant or subsequent injury which is sustained by the intracranial contents; and just as no prudent surgeon would dream of converting a simple fracture of the leg into a compound one for the sake of obtaining an accurate adjustment of the fragments, so the plea for preventive trephining in cases of simple depressed or comminuted fracture of the cranium, without head symptoms, is based upon the supposition that, by operating, the danger of subsequent cerebral mischief will be averted. I can not admit the force of this argument, which seems to me to undervalue, on the one hand, the resources of nature, and, on the other hand, the risks inseparable from

surgical interference. Every surgeon present has, doubtless, met with examples of simple depressed fracture, in which no alarming head-symptoms were present, and in which permanent recovery took place without any active treatment. Surgical literature abounds in such cases. Textor cites twelve instances of depressed fracture verified by post-mortem examination, in seven of which the depression was complete, involving both tables, and in all of which recovery had taken place without any impairment of the cerebral functions. Similar observations have been recorded by Erichsen, Nunn, Bruns, and many other trustworthy writers.

In cases of simple comminuted fracture, without marked depression, but with considerable displacement of the fragments, early trephining is sometimes advocated, on the ground that, unless the loose pieces of bone are removed by operation, they will probably become necrosed, and thereby set up fatal intracranial inflammation. But neither of these statements is confirmed by experience. We can rarely feel certain that the comminuted portions of bone, even though freely movable, are completely detached from their vital connections; for they may still be adherent to the pericranium. But, admitting their isolation to be complete, it is conceivable that their vitality might yet be preserved by newly formed attachments to the surrounding parts. In support of this view, I may cite a case lately published by Professor MacEwan, of Glasgow, who, having applied the trephine in a compound depressed fracture of the skull, took a piece of the inner table which had been completely detached, and laid it in the trephine-aperture. The transplanted bone caused no irritation, and the wound healed without any signs of inflammation. Nevertheless, it can not be denied that necrosis may occur under the circumstances above mentioned, although it is comparatively rare when the fracture is simple. It must also be granted that, when occurring, the suppurative action excited by the presence of the dead bone may extend to the membranes of the brain, causing fatal complications. But there are so many recorded examples of necrosis following gunshot injuries of the head, in which very large pieces of necrosed bone have been removed without the occurrence of cerebral symptoms, that preventive trephining can hardly be defended unless it can be shown to be an operation free from serious risk.

The performance of the operation, in cases of simple depressed fracture, without head symptoms, with the object of removing sharp fragments of the inner table which it is assumed may have penetrated the membranes of the brain, or perhaps the brain itself, seems to me also quite unnecessary. It is true that in severe cases of simple fracture the internal table is often very extensively injured; and Bergmann has aptly remarked that a mere inspection of museum specimens might lead one to infer that simple fractures were graver injuries than those which are compound. But clinical experience proves that these extensive osseous lesions are often recovered from without surgical interference.

On the whole, then, it would appear that the apprehensions felt by those who advocate preventive trephining in the circumstances mentioned are scarcely justified by observation. And, if this fact is admitted, the propriety of performing the operation of trephining must be considered as, at

least, very doubtful. If our means of diagnosis were more exact, and if we were able to predict what cases would turn out badly if left to nature, active interference would often be an obvious duty; but, in the absence of such knowledge, it seems unjustifiable to subject the patient to an operation which must convert a simple into a compound fracture, with its attendant dangers of suppuration in close proximity to vital parts. Although a firm believer in the excellence of antiseptic surgery, I regard the unbroken skin as a surer protection to the deeper parts than the best surgical dressing that has yet been invented; and when we remember that, occasionally, even in careful hands, accidents occur in performing the operation, such as wounding the dura mater, or perhaps the brain, or one of the larger sinuses, we have still further reason to follow the conservative method of treatment which is sanctioned by the teaching and experience of the great majority of living surgeons.

The course which should be pursued in cases of simple fracture of the cranial vault, accompanied by head symptoms, is by no means easy to decide. The unknown quantity vaguely expressed by the term "head symptoms" often leaves us quite in the dark regarding the seat, nature, and extent of the traumatic lesions, so that we can not foretell whether the operation of trephining will prove beneficial, useless, or injurious. In endeavoring, however, to arrive at a definite conclusion on this point, there are certain well-known pathological and clinical facts which may sometimes guide us. Compression of the brain resulting alone from a fragment of depressed bone is rarely of long duration. Often, as has been remarked, considerable depression exists without any interference with the cerebral functions; and even when the depressed bone causes symptoms of compression, these frequently disappear gradually as the cerebro-spinal fluid becomes displaced or absorbed, and the circulation in the brain is restored to its natural condition. Hence, even when we trephine successfully in cases of depression, we can not always be sure that the favorable result is due to our intervention. This point is happily stated by Dieffenbach, who records his experience in the following words: "A boy fell from the first story down upon a stone pavement, and received a fracture of the right parietal bone, of which a piece three inches in circumference was depressed several lines in depth. He lay comatose. I trephined him; he recovered; and I believed that I had saved his life by the operation. A year later he fell from the same place, and struck again upon the stone pavement, this time breaking the left parietal bone, just as he had before broken the right one. He recovered without trephining; again I believed that I had saved his life; and I began to think that he had shown much endurance at the time when he survived the operation."

It has been clearly shown that in severe cases of simple depressed fracture, accompanied with marked and prolonged signs of compression of the brain, other lesions usually co-exist, such as contusion or laceration of the brain, or hemorrhagic extravasation, which may take place between the dura and the skull, in the arachnoid cavity, in the substance of the brain, or on its surface, from the vessels of the pia mater. If we except those rare instances in which the

compression is due solely to an extravasation between the dura and the cranium, we shall have no reason to expect that benefit would result from the application of the trephine. So far as the brain substance is concerned, the damage it has sustained is beyond the reach of mechanical aid; its integrity, if restored, will be slowly regained, as in cases of ordinary apoplexy, by absorption of the extravasated blood. And the same process goes on in favorable cases when blood is effused upon the surface of the brain. We have probably all seen examples of coma lasting for days or for weeks after head injuries, but which yet ended in recovery, due, as we may fairly presume, to the gradual disappearance, by absorption, of the extravasated blood. When we consider how large a quantity of blood is often poured out within the cranium in cases of fracture, we can not avoid the inference that the compression which it exerts is far greater than ever occurs from any depression of bone that we should think of treating by operation. In such cases trephining would be useless, either in consequence of the depth of the extravasation or because, being widely diffused over the surface of the brain, the effused blood would not escape through the artificial opening made in the skull. Furthermore, the operation might in some cases prove injurious, by provoking meningitis. In other words, the very facts which have been urged as affording an indication for the employment of the trephine in cases of simple fracture may, in my judgment, be used as an argument against the propriety of the operation. I refer to the gravity of the injury, and the severity of the symptoms. Where the fracture is of great extent, and accompanied with severe contusion or laceration of the brain, or with copious intracranial hemorrhage, it is extremely doubtful whether the trephine can ever be employed with advantage; while the operation must, by increasing the mechanical injury and by favoring the occurrence of suppuration, add not a little to the already existing danger which threatens the patient's life. Perhaps I do not fully appreciate the comparative safety which attends the performance of the operation according to modern antiseptic methods; but I believe that in this class of cases future experience will prove active interference to be of doubtful utility.

There are two conditions, however, either one of which, when present, renders imperative an immediate resort to the trephine. One of these is the case in which the fracture is of limited extent, and in which there is reason to think, from its situation or from the occurrence of monoplegia, monospasm, or hemiplegia, that a splinter from the inner table may have penetrated the motor tract of the cerebral cortex. But, as we have seen, the fractures which are attended with such displacement of fragments of the inner table are usually of small extent, and are almost invariably compound. The other case is the one in which compression of the brain is caused by an accumulation of blood between the dura mater and the cranium. Such an accumulation may result from a wound of one of the larger venous sinuses, but in a large majority of instances it depends on a wound or a laceration of the middle meningeal artery. The accident is most frequently accompanied by a compound fracture; but it may be met with in cases of simple frac-

ture, and occasionally when no fracture is present. When there exists a compound fracture, the blood usually escapes through the external wound, thus rendering the diagnosis easy; but, when the fracture is simple, or when the artery alone is injured, the extravasated blood separates the dura mater from the cranium, and may be poured out in sufficient quantity to cause fatal compression of the brain. The amount of blood thus extravasated may be as much as half a pint. When the brain has not sustained severe injury, and the symptoms of concussion are but slight, the signs of the arterial lesion may be quite characteristic. After a blow has been received, usually in the temporo-parietal region, the patient, although, perhaps, slightly stunned, soon regains consciousness, and exhibits no marked signs of cerebral injury. But, after the lapse of a few minutes, or possibly several hours, symptoms of compression appear, and soon become very marked, the patient often dying within twenty-four hours from the time of the accident. Hemiplegia sometimes occurs before insensibility is complete; and its detection is important, for the reason that a blow upon one side of the head has been known to cause a rupture of the artery on the opposite side. The accident affords a clear and positive indication for the application of the trephine; yet there are but few recorded cases of the operation. Adding one recent case to the list compiled by Bergmann, there are one hundred well-authenticated examples of hemorrhage from the middle meningeal artery. Of these, seventeen ended in recovery, and in twelve out of this number the blood escaped through an external wound. Of the remaining five, one recovered without operation, the diagnosis being confirmed by autopsy when the patient died three years later of pneumonia. The other four recovered after operation, the blood being evacuated through the trephine opening. In one of those cases, that of Hueter, the bleeding artery was secured by a ligature.

The four cases of compound depressed fracture may be related in few words.

CASE II.—A girl, aged fourteen, entered the hospital February 14, 1882, having been kicked on the head by a horse shortly before admission. Compound depressed fracture of frontal bone, just above superciliary ridge. Depressed portion measured half an inch by two inches. Patient unconscious. Trephine applied on outer side of depression by Dr. Parmly, house surgeon, and depressed bone elevated and several loose fragments removed. Catgut drainage; salicylated cotton dressing; wound closed by sutures. Patient became conscious soon after operation, and had no head symptoms afterward. Temperature never rose above 100° F. Discharged, cured, February 28th, fourteen days after injury.

CASE III.—Male, aged twenty-three, entered hospital June 22, 1882. Fifteen minutes previously was kicked by a horse, the injury sustained being a compound fracture of left side of frontal bone, just above superciliary ridge; was able to walk into hospital, and showed no signs of concussion. Right pupil dilated. A portion of bone one inch by three quarters of an inch comminuted and depressed. Ether. By means of trephine, gouge-forceps, and elevator, Dr. Weed, house surgeon, removed depressed fragments

and smoothed off sharp edges of bone, leaving aperture five eighths by one inch and a quarter. Dura uninjured; catgut drainage; silk sutures; iodoform dressing. No bad symptoms. Wound healed, and patient discharged, cured, July 6th, fourteen days after accident.

CASE IV.—A man fell eight stories, and was brought to the hospital, comatose, October 3, 1882. Had compound fracture of the right femur, compound fracture of right parietal bone, and fracture of spine in upper dorsal region, the latter injury not being discovered until after death. Pieces of bone impinging on dura mater removed by Dr. Weed, house surgeon, leaving oval opening one inch and three quarters in length. Patient remained comatose, and died thirty-six hours after admission.

CASE V.—Man, aged fifty; admitted October 22, 1882. While under influence of liquor, fell upon a stove, striking the back of his head, and sustaining a compound depressed fracture in occipital region on left side, just above superior curved line. Depressed bone measured three quarters by one inch and a half. Much comminution of both tables, especially the inner. No head symptoms; no wound of dura. Operation by my assistant, Dr. King. Patient etherized, depressed fragments removed, and the edges of aperture made smooth with gouge-forceps. Catgut drainage; wound washed out, as in previous cases, with five-per-cent. solution of carbolic acid, and closed with silk sutures; iodoform dressing. Patient progressed favorably, and was discharged, cured, November 5, 1882, fourteen days after admission.

Of these four cases it may be observed that the third one was evidently hopeless when admitted, and that any operation under the circumstances was inexpedient. The remaining three are familiar examples of recovery after trephining in compound fractures of limited extent, accompanied with depression and comminution of the bone, but not attended with any signs of serious injury to the brain. I believe that in such cases trephining is plainly indicated, and that many lives, which would otherwise be lost, are saved by the operation, which, by elevating depressed fragments, by removing fragments that are loose or sharp, and by permitting thorough antiseptic irrigation of the wound, reduces to a minimum the risk of intracranial inflammation, so greatly to be dreaded in this class of cases. To insure success, however, the operation should be performed soon after the injury, and with strict antiseptic precautions. I recall an instance in which, many years ago, I unfortunately delayed the operation until the third day, in consequence of the entire absence of head symptoms. When these occurred, I trephined, but lost the patient, who, I believe, might have been saved by earlier interference. If trephining has not been performed soon after the accident, and the wound seems to be doing well, I should consider it objectionable to disturb it at a later period, unless an operation were indicated by the occurrence of decided symptoms pointing to intracranial mischief, as I have seen cases of recovery from compound depressed fracture in which the bone was not elevated. But I do not remember to have met with such an instance except in children, who, as is well known, bear head injuries much better than is the case with adults.

While believing that trephining is to be recommended in all cases of compound fracture in which the depression is marked, but of no great superficial extent, and in all cases of punctured fracture when there is reason to suspect that the internal table is extensively splintered or depressed, I am strongly opposed to active interference when the fracture is of great extent, and when the depression is not limited or abrupt. It is true that these cases are usually fatal; but I am sure that nothing can be gained by the extensive operative procedures that would be involved in any attempt to remedy the displacement. Aside from those cases in which the brain has suffered irreparable damage, I think that in future many successes will be obtained by careful antiseptic treatment of the wound, such as recommended by Lister in the management of compound fracture of the bones of the extremities. The most scrupulous cleansing of the wound, the arrest of hemorrhage, the removal of foreign bodies, loose fragments of bone, and of detached portions of brain matter, if present, followed by proper drainage and dressings, is, in my judgment, the only means which, with our present knowledge, promises any benefit in this nearly desperate class of injuries.

In the two cases that complete my list, trephining was performed at a period remote from the date of the accident.

CASE VI.—William G., aged twenty-six, entered the hospital June 26, 1882. Nine years ago was struck on the head by a piece of slate weighing one pound and a quarter. Became immediately unconscious, and remained in bed several weeks. When consciousness returned, left hemiplegia was observed; this remained nearly complete for seven months, after which it gradually diminished, and nearly disappeared. A few weeks after injury, began to suffer from epilepsy, and has ever since been liable to frequent attacks. Left hand somewhat weak; unable to contract index finger. Patient lively and talkative, but mind evidently impaired. On right side of head, near the parietal eminence, is a depression of bone, about one inch and a quarter in diameter. Its right edge is one inch and a half from median line, and its center just in front of the Rolandic line. Depth of depression at center greater than elsewhere, and estimated to be one quarter of an inch. Scalp over depression marked by a crucial scar, the point of cross ing corresponding with its deepest part.

June 27th.—Operation.—Bone exposed by a crucial incision, and trephine applied just behind margin of depression. Piece removed was 5 millimetres in thickness. By means of gouge-forceps, the depressed bone, as well as that adjacent to it, was removed, leaving a nearly circular aperture measuring $4\frac{1}{2} \times 5$ centimetres. The depressed bone was quite vascular, and was considerably thickened, being 12 millimetres in thickness at its central part. No adhesions between bone and dura; no morbid conditions discovered besides those already mentioned. Wound closed by silk sutures without drainage; iodoform dressing. Before and after operation patient took daily 90 grains of potassium bromide. Recovery took place without a bad symptom, the temperature never exceeding 100° F. The dressing was not changed until the end of a week, when complete union was found to have taken place externally. The scalp was con-

siderably elevated, however, by a fluid accumulation beneath it, which was probably either blood or serum, as it disappeared by absorption in the course of the following week, at the end of which time the patient left the hospital, in about the same condition, as regards want of mental and muscular power, as when he was admitted.*

This case was sent to me by my friend, Professor Seguin, who advised the operation as a last resort, medicine having failed to afford the desired relief. What permanent benefit will result from the removal of the depressed and thickened bone it remains to be seen; yet I anticipate little, if any. It seems far more rational to ascribe the patient's symptoms to textual alterations in the cerebral convolutions, resulting from the primary injury, than to assume that they were due to the slight diminution in the size of the cranial cavity, caused by the depressed and hypertrophied bone. Twenty years ago I assisted Professor Willard Parker in operating on an epileptic girl, who had been subject to the paroxysms since her early childhood, and who had a well-marked hypertrophy of the parietal bones, situated near the vertex. The bone was an inch in thickness at its middle part, and projected both externally and internally, the internal projection being estimated to be three eighths of an inch beyond the normal plane of the internal table of the skull. The tumor was completely removed, leaving a circular aperture which was two inches in diameter. The dura mater was healthy, and not abnormally adherent. Recovery from the operation was speedy and satisfactory; but a month later the fits returned, and six months afterward became as frequent and violent as before. In this case there was no history of injury, and, therefore, there was greater reason to hope that an operation would prove beneficial.

CASE VII.—Margaret F., aged thirty-nine, married (?), was sent to me by Dr. R. W. Amidon, who saw her early in November, and has furnished the following notes of the case: "Bright's disease," three to four years ago (swollen feet, backache); was sick nine months. Five weeks ago struck head (left parietal region) against sharp corner; was knocked down and dazed, but not stunned; no fit at time; no signs of fracture or concussion; thinks there has always been a lump there since.

"Two weeks after injury had a 'fit'; lost consciousness, and fell. Since then, at intervals of about a week, has had short epileptic attacks, preceded by queer feeling in tongue, sensation of pins and needles in right hand; then an inversion of right hand, and loss of consciousness; a fall, tongue bitten, etc. Loss of consciousness very short—three to four seconds. Afterward feels weak, and sleeps. Thinks that right hand has lost strength; has headache in right fronto-parietal region; denies syphilis; on examination, right side of face weak; tongue straight when protruded; grasp of left hand nearly as strong as right (25–30); a doubtful limp in right leg; tenderness over site of in-

* A letter dated March 25, 1886, has just been received from the patient's father, stating that the operation has been followed by some amelioration of his condition, the epileptic seizures being somewhat less violent, the headache less intense, and the weakness of the right hand less marked.

jury, which patient indicates as over middle third of ascending parietal convolution; slight aortic direct murmur; ophthalmoscopic examination shows optic disc not choked.

"*Diagnosis.*—Traumatic epilepsy.

"*Treatment.*—Potassium bromide.

"*November 13th.*—Sent to Dr. Sands for operation."

December 18th.—Has been under treatment with bromide of potassium, in ten-grain doses, t. i. d., for some time. Has severe headaches, and at times a piercing pain just at the point of injury. Has had no convulsive attack since admission, and has been going about the hospital ward. Discharge improved.

January 13, 1883.—Readmitted. Has pain on left side of head. Is aphasic at times, and shows some loss of power in both arms. Has fits, and during the fits says she froths at the mouth and bites her tongue.

16th.—Last night had a severe headache, and could not sleep on account of pain.

17th.—Slight facial paralysis of right side. Naso-labial fold narrowed. The tongue in protruding deviates to the right side.

18th.—Both pupils dilated to one fifteenth of an inch. The left pupil contracts moderately on exposure to light. The right less so. Neither responds perfectly.

20th.—Is very stupid, and sleeps most of the time. Ordered sol. potass. brom. 3 j every four hours.

29th.—More aphasic. Has an acne-eruption over face, probably due to potass. bromide.

February 1st.—Examination with ophthalmoscope shows choked optic disc on both sides. Dynamometer shows left hand 30 and right hand 26. No exact diagnosis was made either by Dr. Amidon or myself as to the character of the lesion presumed to exist; but we agreed that an explorative operation would be proper, in the hope of discovering a detached splinter of bone from the inner table, a chronic abscess, or some other morbid condition admitting of relief by mechanical means.

6th.—Ether; operation; Dr. Sands.

The scalp being shaved, an incision was made on left side of head, about two inches above the ear, in a direction parallel to the zygoma. The incision was about two and a half inches long. The largest sized trephine was applied nearly opposite the Rolandic line, and a button of bone removed, about a quarter of an inch thick. Nothing was found, excepting that the dura mater was apparently thickened. The incision was extended for about an inch in a direction downward and outward, and the trephine aperture enlarged by means of gouge-forceps. Pulsation of dura absent; no fluctuation could be felt. A large hypodermic needle was thrust through the dura in three different places to the depth of an inch, but nothing withdrawn. In making two of the punctures, however, the needle met with considerable resistance, and the idea of a tumor was suggested. When all bleeding had stopped, wound was closed with fine catgut sutures, except at upper part, which was left open. Iodoform dressing.

9th.—Patient speaks very indistinctly, and not loud enough to be heard at any distance. Was reported as be-

ing delirious last night. Apparently more aphasic than before the operation.

10th.—Less aphasic.

11th.—Patient delirious at times. P. M., patient very noisy, and disturbs the ward. Magendie's solution, \mathfrak{u} x.

12th.—Patient had to be tied in bed on account of delirium. 3.30 P. M., wound dressed under spray, and found to be perfectly clean. Union had taken place throughout. Redressed with carbolized oil, 1-12.

13th.—Slept tolerably well last night. This morning is very delirious. Magendie, \mathfrak{u} x, administered hypodermically.

14th.—Patient this morning was cyanotic. Respiration, 7; pulse, 120 and strong. Pupils contracted and not responsive to light. Ordered atropine sulph., gr. $\frac{1}{15}$. After taking one dose, respiration, 16. Took two more doses before 12 M. After this time, respiration, 4. 2 P. M., respiration, 5; pulse, 140. At 11 P. M., died. Temperature, after operation did not exceed 99°, until the day before death, when it suddenly rose to 103° F.

Report of autopsy by Dr. Delafield:

"*Body.*—Fat.

"*Head.*—A wound upon left side of head which has united, though not firmly, throughout. The wound runs from about two inches above the ear forward parallel with the zygoma. Beneath this the bone has been removed. The wound in the bone is in the left parietal bone near its lower edge. The upper margin of the squamous portion of the temporal bone has been cut through. The opening through the bone is about one inch and a half long, three quarters of an inch broad. The edges are clean cut. The space thus left between the scalp and the dura is filled with some reddish, partly organized clot, and there is a very little pus at its edges and in the upper fibers of the temporal muscle. The dura beneath is adherent to the pia.

"*Brain.*—The portion of dura adherent and just under the wound lies over the middle of the posterior central convolution, and extends a little posterior to it. The fissure of Rolando is not touched by it, but lies a few lines in front. There seems to be no meningitis.

"Just beneath adherent dura, in posterior central convolution, and in convolution just behind it, is a gummy tumor about one inch in diameter.

"*Heart, liver, spleen, lungs, kidneys, and stomach* are normal.

"Fallopian tube of left side terminates in a cyst containing a fetus."

On reviewing this interesting case in the light of the post-mortem revelation, which seems to indicate a syphilitic origin of the cerebral tumor, it is certainly a subject of regret that the true nature of the disease escaped observation during life, as possibly it might have been controlled by specific treatment. But neither Dr. Amidon nor myself was able to obtain a syphilitic history, or to discover any existing specific lesion. Certainly the symptoms were very misleading. No convulsive seizure or other sign of cerebral trouble preceded the injury to the head, which was inflicted directly over the psycho-motor centers, and which was followed, after the lapse of a fortnight, by epileptiform attacks

in which the convulsive movements were strictly limited to the upper extremity on the side of the body opposite to that where the blow was received. Assuming the morbid growth, however, to have been syphilitic, it must be a matter

FIG. 1.—LATERAL VIEW OF THE BRAIN, showing the position of the Tumor.

of conjecture whether the injury acted as an exciting cause and determined its development, or whether the causative relation was the reverse, the injury having been due to a fall which occurred when the first epileptic fit was occa-

upper extremity; but, as the affection of the upper limb was observed some time before the other nervous disturbances occurred, it was believed these latter symptoms were due to secondary changes, perhaps to pressure or œdema, and that the primary cause would probably be found in the center governing the movements of this part of the body. The post-mortem examination verified the accuracy of this conclusion, and the accompanying drawing, furnished by the pathologist, Professor Delafield, shows that the tumor occupied the center referred to, and that it lay directly beneath the opening made by the trephine. Finally, although the autopsy disclosed no evidences of cerebral inflammation excited by the operation, the active delirium which set in toward the close of life may possibly have resulted from encephalitis; and it seems certain that death, although inevitable, was hastened by the undue effects of a dose of morphine, administered with the object of relieving this distressing symptom.

MEDICAL ETHICS AND ETIQUETTE.

COMMENTARIES ON THE NATIONAL CODE OF ETHICS.

By AUSTIN FLINT, M. D.

Sixth and Concluding Article.

OF THE DUTIES OF THE PROFESSION TO THE PUBLIC, AND OF THE OBLIGATIONS OF THE PUBLIC TO THE PROFESSION.

ART. I.—Duties of the Profession to the Public.

SECTION 1. As good citizens, it is the duty of physicians to be ever vigilant for the welfare of the community, and to bear their part in sustaining its institutions and burdens; they should also be ever ready to give counsel to the public in relation to matters especially appertaining to their profession, as on subjects of medical police, public hygiene, and legal medicine. It is their province to enlighten the public in regard to quarantine regulations—the location, arrangement, and dietaries of hospitals, asylums, schools, prisons, and similar institutions—in relation to the medical police of towns, as drainage, ventilation, etc.—and in regard to measures for the prevention of epidemic and contagious diseases; and, when pestilence prevails, it is their duty to face the danger, and to continue their labors for the alleviation of the suffering, even at the jeopardy of their own lives.

SECTION 2. Medical men should also be always ready, when called on by the legally constituted authorities, to enlighten coroners' inquests and courts of justice on subjects strictly medical—such as involve questions relating to sanity, legitimacy, murder by poisons or other violent means, and in regard to the various other subjects embraced in the science of medical jurisprudence. But in these cases, and especially where they are required to make a post-mortem examination, it is just, in consequence of the time, labor, and skill required, and the responsibility and risk they incur, that the public should award them a proper honorarium.

SECTION 3. There is no profession by the members of which eleemosynary services are more liberally dispensed than the medical, but justice requires that some limits should be placed to the performance of such good offices. Poverty, professional brotherhood, and certain of the public duties referred to in the first section of this article, should always be recognized as presenting valid claims for gratuitous services; but neither institutions endowed by the public or by rich individuals, societies for

FIG. 2.—TRANSVERSE VERTICAL SECTION OF THE LEFT CEREBRAL HEMI SPHERE, showing the relation of the Tumor to the Trephine Aperture.

sioned by the already existing gummy tumor. The case is instructive as demonstrating the value of cerebral localization in determining when the trephine should be applied. At the time of the operation the patient suffered from aphasia, impairment of vision, facial paralysis, and partial paralysis of the tongue, as well as from paresis of the right

mutual benefit, for the insurance of lives or for analogous purposes, nor any profession or occupation, can be admitted to possess such privilege. Nor can it be justly expected of physicians to furnish certificates of inability to serve on juries, to perform militia duty, or to testify to the state of health of persons wishing to insure their lives, obtain pensions, or the like, without a pecuniary acknowledgment. But to individuals in indigent circumstances such professional services should always be cheerfully and freely accorded.

Laudation of the medical profession by physicians for the public may not always be consistent with a proper degree of modesty, but laudation of the profession for its members is not only admissible, but it has a salutary influence. The more physicians are led to regard medicine in its humane and noble aspects, the more they are reconciled to its hardships, and the more they are incited to do all in their power to maintain its character and usefulness. The feeling that honor is reflected by membership of a profession which professes to be governed by the code of medical ethics conduces to a high moral tone, and it is in this way that the code is of great service. It is a beautiful feature of the code that it aims solely at the influence of its ethical rules on the mind, irrespective of any penalties. It is based on the principle that moral rectitude is promoted more by fostering upright sentiments than by the punishment of offenses.

Comments on the duties of physicians, as good citizens, to the public may fairly furnish an occasion for laudatory reflections. In all measures relating to the health and welfare of communities, physicians have been foremost. They have always been found ready to devote knowledge, time, and efforts to these objects. Most medical associations are formed in great part for the purpose of considering and carrying out measures for the promotion of public health. "The American Public Health Association," which was formed in 1872, has for its sole objects "the advancement of sanitary science and the promotion of organizations and measures for the practical application of public hygiene." Members of this association, from all the States of the Union, are, for the most part, medical men. They attend annual meetings, prepare papers which are published in an annual volume of Transactions, and contribute funds for all the expenses of the association. Voluntary law associations, sustained by the medical profession, for the same objects, exist in different parts of the Union. There are not a few medical men in this country whose professional labors are devoted especially, or chiefly, to sanitary science or hygiene, with no expectation of compensation except the satisfaction of having contributed to the promotion of public health or the welfare of the communities in which they live. May we not claim that for these things the medical profession is deserving of praise?

In claiming for the profession praise for the performance of duties to the public, it is not intended in the least to depreciate the binding force of these duties as such. They are so recognized. Within late years, to the study of sanitary science and hygiene has been allotted a distinct department of medicine. Preventive medicine, as this department is called, now holds a prominent place in medical

literature, as well as in the labors of medical men. Recent developments in etiology have already led to most important results as regards the prevention of diseases, and there is reason to believe that these developments are the earnest of those still more important. Few, if any, of those who have given attention to the subject will doubt that in the medicine of the future more is to be expected from the application of knowledge to prophylaxis than to therapeutics. It is needless to add that physicians are morally bound to become acquainted with important facts and laws relating to sanitary science and hygiene as they are developed, in order thereby to be able to fulfill properly their duties to the public. They who are engaged in investigations relating to etiology and pathology are bound to consider and follow out, as far as practicable, the bearings of these on the health and welfare of communities.

It may be said, in the way of laudation, that there are very few instances in which members of the medical profession desert the post of duty in consequence of the danger which may be therewith connected. They generally "face the danger," whether it be on the field of battle or when a pestilence prevails. The profession is entitled to whatever of praise belongs to courage in the performance of professional duty, albeit the courage has no recompense beyond the satisfaction of having followed the dictates of duty. The physicians' roll of honor is the list of those who have died in the performance of professional duty. The history of every epidemic disease furnishes such a list. The risk of life was simply a duty, but who will refuse to accord to it nobleness? Who would remove from the code that portion which enjoins upon physicians that, when pestilence prevails, "it is their duty to face the danger, and to continue their labor for the alleviation of the suffering, even at the jeopardy of their own lives"?

A broad distinction, in respect of pecuniary acknowledgments, exists between the duties which every physician owes to the public in behalf of matters embraced in preventive medicine and the duties connected with the legal administration of justice. Whenever called upon by legally constituted authorities to give advice or expert testimony at coroners' inquests or in courts of justice, in relation to medical questions, physicians should be paid for their services. In view of the services rendered to the public without compensation, for those just referred to there should be adequate pecuniary acknowledgments. Investigations in cases of supposed insanity, of homicide by poisons or other means, etc., and post-mortem examinations, made under instruction by authorities, claim ample remuneration. There is no good reason for physicians being expected to perform these duties gratuitously. Much injustice is often done to the medical profession in regard to these duties. Physicians should not fail, from a false sense of delicacy, to assert their rights in this regard, and they should endeavor to lead the public to recognize the propriety of so doing.

The foregoing remarks concerning those duties to the public for which physicians should receive adequate remuneration will apply equally to certain professional services rendered to institutions and to individuals. These services are referred to in the third section of the article of

the code which relates to the duties of the profession to the public. That these services should be rendered gratuitously seems to be expected, because those which are purely eleemosynary are recognized as such by the profession. Now, this is a good reason for not rendering the services without payment. They are in no sense eleemosynary in their character. It should be generally understood by members of the profession, as well as by the public, that they are to receive pecuniary acknowledgment. A reform in this regard would be of not a little importance to physicians, and the burden on the public would be light. The qualification relating to individuals in indigent circumstances divests the rule of any objection on the score of liberality, and is in accordance with the spirit of beneficence which pervades the entire Code of Ethics.

SECTION 4. It is the duty of physicians, who are frequent witnesses of the enormities committed by quackery, and the injury to health, and even destruction of life, caused by the use of quack medicines, to enlighten the public on these subjects, to expose the injuries sustained by the unwary from the devices and pretensions of artful empirics and impostors. Physicians ought to use all the influence which they may possess, as professors in colleges of pharmacy, and by exercising their option in regard to the shops to which their prescriptions shall be sent to discourage druggists and apothecaries from vending quack or secret medicines, or from being in any way engaged in their manufacture and sale.

Empiricism, in the popular sense of this term—in other words, charlatanism or quackery—has hitherto abounded, and will, doubtless, continue to abound. Its success, depending, as it does, on a peculiarity of certain mental constitutions, is the same at the present time as in the past, and as it will be in the future. The forms of empiricism change with different periods, but the underlying credulity remains unchanged. This credulity has no necessary connection with intellectual endowments, special talents, or extensive acquirements in other branches of knowledge than medicine. Hence, the judgment of those distinguished in law, art, theology, letters, or in business operations, is of no more, and, indeed, of less value than that of persons having good common sense in the middle walk of life.

To enlighten the public on subjects which may be embraced under the name popular medical delusions is not easy. There are difficulties not readily overcome. In the first place, persons fall into these delusions from an intrinsic proclivity thereto, and not as a result of investigation or a logical process of reasoning. Arguments, however cogent, and evidence, however strong, are, therefore, often of no avail. In the second place, efforts to enlighten the public on these subjects by physicians are met by a belief that they are prejudiced and interested parties. In the third place, whenever one has committed himself to an empirical doctrine or system of practice, the feelings of egotism and pride are powerful obstacles in the way to a conviction of error. The mind strives to find support in the opinions which have been adopted, and resists proof against their validity. Hence, in order to gain strength thereby in their opinions, they endeavor to make proselytes. For those who are open to a fair consideration of these subjects, it would seem that

the following points should be conclusive: It can hardly be denied that educated medical men are the most competent to form correct judgments concerning questions which relate to etiology, pathology, and therapeutics. If there be truth in any assumed discovery or improvement in these branches of knowledge, it is plainly for the interest of medical men to adopt them. Sooner or later physicians must accept real discoveries or improvements. Is it not, therefore, the safest policy to be governed by the verdict of the medical profession?

The position taken by the medical profession in regard to secret remedies is not generally understood by the public. It is simply this: If these remedies be really valuable, they should be made known for the benefit of all mankind. They should not be kept secret or patented for personal gain. There should be no mystery connected with them. Surely this position is disinterested, and in accordance with the dictates of humanity. The action advised by the code in regard to druggists and apothecaries who prepare or vend secret nostrums is one which it would be well for physicians to adhere to more strictly than is usually done—namely, to discriminate, in sending their prescriptions, in favor of the shops which have nothing to do with these nostrums. In this way their sale can be discouraged, and something accomplished toward directing the attention of the public to the subject from a proper point of view.

Within late years a custom has arisen and become largely prevalent among pharmacutists which should be discountenanced by the medical profession. Reference is had to the diversity of medicinal preparations compounded of different drugs, and extensively advertised for the use of physicians and the public. These are now known as "proprietary medicines." A legal right of proprietorship is secured and held by vending them under a trade-mark. The custom is objectionable for several reasons. It encourages a popular use of drugs without medical advice. The use of these medical compounds interferes with the combinations by physicians in adaptation to indications in individual cases of disease. Their use interferes with accurate observations of the effects of particular drugs. Finally, there can be no guarantee that the preparations are what they purport to be. As a rule, the best policy with reference to the welfare of patients and to experience in therapeutics is to prescribe potential remedies separately, rather than in combination, and, when prescribed in combination, to give preference to official preparations. It is not denied that some of the so-called proprietary remedies are useful, and it is not intended by these remarks to imply that new remedies are not to be properly tested by clinical observations. There is a manifest impropriety in giving certificates recommending any of the multitudinous pharmaceutical compounds with which the country is flooded. If a physician have been led by his experience to form a favorable opinion of any one of these, or of a new remedy, the proper channels of communication with the profession is through the medium of medical books or journals. Communication with the public by certificates or articles in newspapers is in violation of the Code of Ethics.

ART. II.—*Obligations of the Public to Physicians.*

SECTION 1. The benefits accruing to the public, directly and indirectly, from the active and unwearied beneficence of the profession, are so numerous and important that physicians are justly entitled to the utmost consideration and respect from the community. The public ought likewise to entertain a just appreciation of medical qualifications; to make a proper discrimination between true science and the assumptions of ignorance and empiricism—to afford every encouragement and facility for the acquisition of medical education—and no longer to allow the statute-books to exhibit the anomaly of exacting knowledge from physicians, under a liability to heavy penalties, and of making them obnoxious to punishment for resorting to the only means of obtaining it.

The claims of the medical profession to the consideration and respect of the community have been already commented on sufficiently in connection with other portions of the Code of Ethics. A just appreciation of medical qualifications by the public is desirable as an incentive to members of the profession to aim at these, and as a reward for their possession. In these points of view, it is discouraging to the votaries of true science for the assumptions of ignorance and empiricism to be successful in obtaining popular distinction. The public can not be expected always to judge correctly between real qualifications and false assumptions. True distinction in medicine, therefore, must be based on the opinions of unbiased medical men.

The apathy and indifference on the part of the public to medical education is a singular incongruity, in view of the immense importance of well-educated physicians to every community. The interests of medical education are left almost wholly to physicians, whereas these interests concern the public vastly more than the medical profession. If the public could be made to see this subject in a proper light, there would be no lack of accommodations, provisions, and appliances for all the departments of medical instruction. The last sentence of the Code of Ethics refers especially to the absence of legal enactments in behalf of the practical study of anatomy. Since the adoption of the code in 1847, much has been accomplished, chiefly by the efforts of physicians, in the legalization of this study and the provisions for obtaining subjects for dissection. In many parts of the Union, however, much is yet to be accomplished. Let the public consider that, if adequate laws be enacted, there will be no occasion for occurrences which naturally and properly shock the feelings of a community. Let it also be considered that the public welfare is promoted by affording all proper facilities for clinical study and teaching, by encouraging pathological investigations, by refusing sympathy with the pseudo-humanitarians who would interdict experimental researches upon the lower animals, and by bestowing honorable distinction on those who are justly deserving of it. The public welfare is promoted just in proportion as thereby medical science is advanced and medical education improved. The time will come when not only public authorities will appreciate the importance of co-operating with the medical profession in behalf of the interests of medical science and education, but private munificence will take this direction. For the cause of humanity, as well as the honor

of the profession, a full recognition of the obligations of the public to physicians is a "consummation devoutly to be wished."

(To be concluded.)

POPLITEAL ANEURYSM TREATED WITH ESMARCH'S BANDAGE. EXTENSIVE NECROSIS OF THE TIBIA—AMPUTATION AT THE KNEE JOINT. AMPUTATION AT THE KNEE JOINT FOR COMPOUND FRACTURE OF THE LEG. INTERNAL URETHROTOMY FOR STRICTURE OF THE URETHRA.

Clinical Remarks

By ROBERT F. WEIR, M. D.

I.

(Reported by R. C. SHULTZ, M. D.)

CASE I.—POPLITEAL ANEURYSM TREATED BY THE ESMARCH BANDAGE.

GENTLEMEN: This patient whom I now show you is a Chinaman, forty-three years of age. He has a popliteal aneurism, but he gives no history of any disease that is said to induce weakness of the coats of the arteries, such as syphilis, etc.; but he states that, in consequence of a severe strain more than two years ago, the leg being at the time forcibly extended, he felt sudden pain in the right knee; afterward he observed swelling and pulsation in the popliteal space. Within the past few weeks this swelling has rapidly increased in size, and the pulsation, which is synchronous with the heart-beat, has become much more distinct. Pressure upon the femoral artery above arrests pulsation in the tumor in some degree, and causes a diminution in its size. These facts point conclusively to an aneurysmal dilatation of the artery in the popliteal space. The loud bruit which can be heard over the tumor is due to the passage of blood over deposits of fibrin, and would point to a sacculated rather than a spindle-form dilatation of the coats of the vessel. Experience also tells us that the former condition is the one usually met with in the locality.

The plan of treatment which it is proposed to adopt in this case is, if possible, to arrest the circulation of the blood through the tumor sufficiently long to admit of coagulation and the formation of a clot. The principle upon which the treatment is based might be considered at first sight the same as that adopted many years ago. Up to quite a recent period the endeavor on the part of surgeons was to imitate nature and fill the sac of an aneurysm by masses of fibrin. This was accomplished mainly by slowing the current of blood through the aneurysm by either ligating or compressing the artery nearer the heart. By the former procedure the collateral circulation allowed blood, it was said, to flow gently through the aneurysm until it became filled with the desired firm clot in which fibrin predominated. By compression of the main artery above the aneurysm, generally carried on intermittently, the same thing was accomplished. A number of cases occurred, however, in the practice principally of the Irish surgeons, which showed that the complete occlusion of the blood current through an aneurysmal sac from one to four hours was not only free from risk of gangrene, but also that it effected a cure. Aneurysms of the iliac arteries were thus successfully treated by compression of the abdominal aorta. Though a soft ordinary clot was thus shown to answer satisfactorily in permanently consolidating an aneurysm, yet the means of compressing the artery lead-

ing to an aneurysm remained incomplete until the elastic bandage of Esmarch became known to the profession. In 1875, Dr. Walter Reid applied for the first time the elastic bandage to the limb below and above an aneurysmal tumor for sufficient length of time to allow of the formation of a soft blood clot that afterward became hardened and permanent.

The method was originally made use of in a case of popliteal aneurysm; the elastic bandage was applied from the foot to near the site of the tumor, and from just above the tumor to near the commencement of the femoral artery. On removing the bandage at the end of fifty minutes, it was found that the circulation in the tumor had ceased and was afterward carried on collaterally in the parts below. Although the danger from gangrene and secondary hæmorrhage from the old method of treatment by ligation of the femoral artery has been reduced to a minimum since the introduction of Listerism, still this result obtained by Reid may be considered a great advance in the treatment of these cases. This fact is especially and forcibly impressed on us if we refer to the statistics of the old methods of treatment given by Dr. Norris, who found that, out of some two hundred and four cases, gangrene or secondary hæmorrhage had occurred in fifty instances; and an English surgeon found that, out of about sixty cases in which the femoral artery had been tied, gangrene occurred in about one third. The treatment by the Esmarch bandage has now been practiced in about one hundred cases with only fifteen per cent. of failures and two deaths. In one of the cases in which death occurred the bandage had been left on by mistake for seven hours, and gangrene had set in. There was also present fatty degeneration of the heart. The other case was one of Mr. Rivington, of London, in which he made compression of the femoral artery for a considerable time following rupture of the aneurysm, which affected the anterior tibial artery. In another case, that of Mr. Bryant, of London, gangrene occurred in the leg, necessitating amputation, after a ligation of the femoral artery resorted to two weeks after an unsuccessful trial of the elastic bandage.

I will now proceed to apply the Esmarch bandage round this man's leg, commencing at the foot, passing over and not compressing the aneurysm itself, and ending near the groin, where the limb is encircled by two turns of rubber tubing, which, secured by a clamp, acts as a tourniquet. After a few minutes a hypodermic injection of morphia will be given—a large one, because the patient is more or less addicted to the use of opium; and later, when the pain becomes considerable, an anæsthetic will be administered. The rubber bandage will be allowed to remain on fifteen or twenty minutes, and the tourniquet an hour or an hour and a half, when it will be gradually let up to determine whether the circulation through the tumor has ceased; if so, the tourniquet will not be taken off entirely, but the pressure will be slightly kept up by an ordinary Signoroni's tourniquet for an hour longer, when it is hoped the clot will be hard enough to remain permanently. However, should this large amount of coagulated blood afterward become broken down and enter the circulation, the danger will not be so great as one might suppose, for in no case has it yet led to any serious result.

[NOTE.—The patient was brought before the class at the end of the clinic with the aneurysm filled with a solid clot, devoid of pulsation even when the tourniquet was removed. Signoroni's horseshoe tourniquet was directed to be kept on for an hour longer, with very light pressure.]

CASE II.—EXTENSIVE NECROSIS OF THE TIBIA—AMPUTATION AT THE KNEE JOINT.

We have a case here, gentlemen, the outcome of which is somewhat doubtful. It is that of a child eleven years of age,

who, six or seven years ago, received an injury which produced a compound fracture of the right leg. Death of the bone took place to some extent, requiring an operation for its removal. The operation had to be repeated a year and a half later, and again three years ago. At present we find many sinuses discharging pus, and leading down to dead bone. The patient's condition is very low, but I think it advisable to explore these sinuses with the thoroughness afforded by the anæsthesia, and see if the dead bone can not be removed without sacrificing the leg by amputation. We have the more hope of a successful result from the operation for removal of the necrosed portion of bone in this case since there are no indications of the presence of kidney disease. I do not think, however, that the presence of the symptoms of kidney trouble constitutes so strong a contraindication to the operation as was at one time supposed, for it has been found in several instances that the renal symptoms, presumably from amyloid disease, disappeared with the arrest of the discharge from the wound following the operation. On cutting down upon the bone, I find that the entire shaft of the tibia is involved; and, moreover, the periosteum is diseased so extensively that no attempt has been made toward repair. There is not the slightest appearance of an involucrum. I will make a perforation of the bone; by this I see that the entire shaft of the bone is dead, that its cavity is filled with pus. These conditions, conjoined with the septic symptoms of rapid pulse, and temperature elevation to 104°, convince me it would be worse than useless to try to save the leg. We will, therefore, proceed to amputate at the knee joint, and, if it is impossible to get a sufficient amount of flap not affected by the disease, the end of the condyle will be cut off. You will observe, having, fortunately, sufficient flap for an exarticulation, that I open up the upper synovial pouch of the joint on each side thoroughly and insert a drainage tube, so that there shall be no opportunity for the collection of matter in this cavity. This avoids the tendency to abscess met with in this amputation. The drainage tube used is the deacidified bone of Neuber. We apply carbolized peat dressing, hoping to avoid the necessity of changing it frequently, which sometimes happens when the Lister dressing is used alone, and thus to secure as long as possible perfect rest to the stump, and so help to a rapid union. Pathological amputations usually give better results than where amputation is performed immediately after the receipt of an injury. We hope to be able to show you this patient in a much improved condition at a future clinic.

CASE III.—AMPUTATION AT THE KNEE JOINT FOR COMPOUND FRACTURE OF THE TIBIA.

This patient is a man of irregular habits, aged fifty years, who fell from a ladder on the 22d of December, 1882, and sustained a compound fracture of the leg near the ankle. The fractured bone was dressed with an antiseptic dressing, as is usual in such cases, but, unfortunately, it was not ascertained until a day or two later that the ankle joint had been involved in the injury; otherwise a somewhat different method of drainage might have been adopted. The antiseptic treatment, so far as it could be carried out under the circumstances, failed, suppuration took place freely, the temperature rose, and the patient's condition deteriorating, amputation of the limb was suggested, but the patient refused it. Afterward, diarrhœa, delirium, and elevation of temperature (103°) set in. Evidences of sepsis occurred, and removal of the limb was consented to yesterday; and we shall proceed to do this operation to-day. Did time permit, this would be a suitable occasion to refer to some points in regard to when conservative surgery should be abandoned in the treatment of compound fractures and amputation resorted to. I can only state at present that in a case like this, when the temperature begins to rise at night and to fall again in the morn-

ing, when the patient begins to lose flesh rapidly, when he is more or less delirious at night, and, when the bowels begin to move pretty freely and are not readily checked, it is full time to proceed at once to amputate the limb. Amputation in a patient under the conditions of the present one is much more serious than in the preceding one, not only because of the difference in the ages, but because, unlike in the former case, the disease has not existed for months and years, giving rise to a degree of toleration, but is comparatively recent, and amputation will only be a source of additional shock. The rule holds good in this case, that the more remote from the trunk the amputation is performed the less is the risk to the patient's life, and we shall amputate as low down on the limb as possible, consistent with a sufficient amount of healthy skin for a flap. The results of amputations after symptoms of blood-poisoning had set in, in olden times, were much worse than at present. Billroth has said that out of fifty amputations made at his clinic after septicæmia had declared itself, only seventeen of the patients died—a remarkably good result. We hope to be equally favored in these cases.

CASE IV.—INTERNAL URETHROTOMY FOR STRICTURE OF THE URETHRA.

The last patient upon whom we will operate to-day is a man who is suffering from moderate retention of urine due to a stricture, the result of a gonorrhœa contracted about twelve years ago. About two years later the patient noticed that the stream passed was not so large as usual; he micturated frequently, had suffered from pains in the region of the bladder, and in the back and legs. Retention has never been of long duration, but he has at times found it necessary to strain considerably in order to pass his urine. On introducing an instrument, we find the distance down to the site of the stricture to be about five inches and a half, or nearly three quarters of an inch anterior to the triangular ligament. I may remark here that it is important, in passing an instrument, to determine the depth and seat of a stricture, to pass one finger into the rectum at the same time in order to determine the relation of the stricture or point at which the instrument is obstructed to the apex of the prostate gland. The importance of this precaution will be evident if we suppose extravasation has occurred, forming a perineal tumor, for, by estimating the distance upon the sound alone you may suppose the stricture to be more deeply situated than it is in fact, that it lies beyond Buck's fascia, and that the extravasation has therefore taken place backward. But remember, gentlemen, that in the great majority of cases, the statement of some text-books to the contrary notwithstanding, the seat of close deep strictures is just anterior to the triangular ligament, and when extravasation takes place it does so anteriorly, and the tumor formed thereby should be opened at once without hesitation.

Yesterday we were able to pass a small flexible bougie beyond the stricture; to-day we find it impossible to do so, and it is only after a great deal of difficulty that we have been able to pass a whalebone bougie. You have observed the tendency which the bougie had to enter a follicle near the stricture and to become arrested; by first filling the urethra with oil and then passing one bougie after another, and leaving them in position until the follicle would contain no more, we were at last enabled to pass one through into the bladder. The peculiar grasp which the stricture gives to the bougie while the patient is under the influence of an anæsthetic is pathognomonic, and indicates an organic, not a spasmodic, stricture. Indeed, this biting may be considered as pathognomonic of organic stricture, even when the examination is made without an anæsthetic; at least I have never known it to be produced by any other than an organic stricture.

There are two principal methods of treating cases of urethral stricture such as the one before us to-day, and the opinion

of surgeons with regard to the relative value of these two methods varies greatly. In the one case the treatment consists in the passage of instruments of increasing size every two or three days for some time, with the object of dilating the constriction; the other method is to pass a cutting instrument and divide the constriction to the proper size at once. It has been claimed for the former method that it is the safer, but the validity of the claim is very doubtful. In a series consisting of five hundred and sixty-five cases, collected by Mr. Bryant, it has been found that the mortality by dilatation is six per cent. Grégory, however, gives a table of eight hundred cases of internal urethrotomy, with forty-six deaths, or a mortality of 5.66 per cent. Dilatation certainly possesses this disadvantage: that it is not infrequently followed by urethral chill and fever, much less so than urethrotomy is. I have never in private practice, among patients who are able to take proper care of themselves, lost a single case after internal urethrotomy. As much can not be said for hospital practice, for there the patients are often in a condition anything but favorable. I believe that in a young subject, like this man, whose health is good, in whom there is no evidence of kidney or bladder trouble in any marked degree, internal urethrotomy is not only as safe as dilatation, but that it effects relief much more promptly, the patient is able to return to his business much more quickly, and I also believe that the danger of recontraction is postponed much longer than after dilatation. Reconstriction, however, will, in all probability, take place sooner or later; I have seen it occur in so many cases that I expect it as a rule, and warn the patient of the danger. Even in external urethrotomy, which was practiced very extensively in these cases some forty years ago, and in which the stricture was completely divided throughout its whole extent, reconstriction took place, just as it does now, after the operation of internal urethrotomy.

We shall divide this stricture by passing a Maisonneuve urethrotome with a tunneled end over the whalebone bougie that has been introduced into the bladder. A cutting blade eleven millimetres in width will be employed, dividing the strictured portion along its upper surface sufficiently as it enters to admit a No. 26 sound; then turning the instrument slightly, another incision will be made as it is withdrawn, after which we hope to be able to pass a sound of full size. I do not state positively that we will be able to do so, for sometimes the elasticity of the stricture is such that the instrument may fail to make an incision corresponding to its full size. You will observe that in this case we have succeeded in dividing the stricture thoroughly; a No. 34 sound passes without difficulty, although it must be remembered that the patient is under the influence of ether. Reference is made to about No. 32 or 33 as the normal size, and not to the rule laid down by Dr. Otis, that the size of the urethra corresponds to that of the circumference of the penis—a rule to which I believe there are many exceptions. Only very recently a patient presented himself whose penis measured only three inches and a quarter in circumference, while the urethra admitted a No. 41 sound.

With regard to the use of quinine for the prevention of urethral chill, I have found it of very little efficacy, and this experience is confirmed by that of Malherbe, a French observer, who has investigated the matter thoroughly. A better result is obtained, I think, from the administration of three or four minims of the tincture of aconite with an eighth of a grain of morphia, every three to six hours for the first day, to be repeated if a chill comes on, and alkalies for their effect upon the urine. Further precautions may be necessary where kidney trouble is threatened. No attempt is to be made to introduce a sound into the bladder for at least four days, and only then if the temperature be normal.

Book Notices.

Lehrbuch der Hautkrankheiten. Für Aerzte und Studierende bearbeitet von Dr. GUSTAV BEHREND, Privatdocent an der königl. Universität in Berlin. Zweite vermehrte Auflage, mit 43 Holzschnitten. Berlin: August Hirschwald, 1883. Pp. xii-612.

THIS second edition of Behrend's work (the first having been published in 1879) is a great advance upon the old, both in size—it now appearing as an octavo, whereas in the first it was in duodecimo form—and in its general appearance; the text is amplified, and the illustrations are more numerous, a fair proportion of the latter being original. In short, it makes a handsome volume, in the place of one having the appearance of a mediocre manual.

Treatises on dermatology have become so numerous of late that no such field is possible as in the times of the elder Hebra, of Wilson, or of Hardy, so that we can no longer look for any great originality of thought in such works; authors on these subjects must be content with the rank of good compilers. In the volume before us, however, we think German thought on dermatological matters has one of its best, if not its very best exponent. We consider it excellent in conciseness and clearness of method and diction, while its faults, or rather omissions, are few in number, and are those of all German writers on the subject, consisting chiefly in the relatively imperfect consideration of therapeutics and symptomatology. Of local and mechanical therapeutic means enough is said, and methods are mentioned which certainly must always be dead letters here, for patients in this country can not be brought to submit to the treatment. Again, many medicaments, both for internal and for external use, are either dismissed with a slighting reference or not mentioned at all; for instance, the oleates of the various metals, phosphorus, ergot, calx sulphurata, the various preparations of the strychnos family, gurjun and chaulmoogra oils, and many others.

The chapter on the anatomy, and that on the physiological functions, of the skin, though brief, are admirably given; and the pathology of the different skin affections deserves the same praise. The classification of Hebra is retained with unimportant modifications.

We are pleased with some of Behrend's deviations from the teachings of the Viennese school in certain directions—as, for instance, in the etiology of varicella, lupus, etc.—the Viennese school insisting on the identity, or at least the close relationship, of the first named with variola, which Behrend entirely denies.

In short, the volume as a whole is a strong, well-written work, which we should be glad to see translated, and so given to the non-German-reading medical public.

BOOKS AND PAMPHLETS RECEIVED.

The Diseases of Women. A Manual for Physicians and Students. By Heinrich Fritsch, M. D., Professor of Gynecology and Obstetrics at the University of Halle. Translated by Isidor Fürst. With 159 wood engravings. New York: William Wood & Co., 1883. Pp. vi-355. [Wood's Library of Standard Medical Authors.]

First Annual Report of the State Board of Health of Indiana. For the fiscal year ending October 31, 1882. [Thad. M. Stevens, M. D., Secretary and Executive Officer, Indianapolis.]

First Annual Report of the Board of Health of Kansas City. For the calendar year 1882. [From Dr. John Fee, City Physician.]

De l'emploi de la résorcine dans le traitement du chancre simple chez la femme. Par MM. les docteurs A. Leblond et Fisiaux. Pp. 8. [Reprint from the "Annales de gynécologie."]

The Photography of Microscopic Sections. By James Whitson, M. D., etc. Pp. 5. [Reprint from the "Glasgow Medical Journal."]

Ninety-third Annual Report of the Board of Trustees of the New York Dispensary. January, 1883.

Thirty-sixth Annual Commencement of the Starling Medical College. Address by Professor Loving to the Graduating Class. Columbus, 1883. Pp. 15.

Lectures on Orthopædic Surgery and Diseases of the Joints, delivered at Bellevue Hospital Medical College, during the winter session of 1874-'75. By Lewis A. Sayre, M. D., Professor of Orthopædic Surgery and Clinical Surgery, etc. Second edition, revised and greatly enlarged, with 324 illustrations. New York: D. Appleton & Co., 1883. Pp. xx-569.

Student's Guide to Diseases of the Eye. By Edward Nettleship, F. R. C. S., Ophthalmic Surgeon to St. Thomas's Hospital, etc. Second American, from the second revised and enlarged English edition. With a chapter on Examination for Color Perception, by William Thomson, M. D., Professor of Ophthalmology in the Jefferson Medical College. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. xix-13 to 416, inclusive.

Manuel des injections sous-cutanées. Par Bourneville, médecin de Bicêtre, et Bricon, docteur en médecine. Paris: Librairie du Progrès médical, 1883. 12mo. Pp. xxxvi-174. [Prix: broché, 2,50f.; cartonné, 3f.]

Ueber den respiratorischen Gasaustausch beim fiebernden Menschen. Von Prof. Dr. Gustav Wertheim, k. k. Primararzt. Pp. 11. [Separat-Abdruck aus den "Mittheilungen des wiener medicinischen Doctoren-Collegiums."]

Ueber die Aenderungen der Leistungsfähigkeit und der Erregbarkeit des ermüdenden Frosherzens. Von Dr. Th. Mays. Pp. 6. [Separat-Abdruck aus den "Verhandlungen der physiologischen Gesellschaft zu Berlin."]

Fifth Annual Report of the Managers of the Adams Nervine Asylum, 1882.

Proposed Ordinance and Rules and Regulations for Regulating the Plumbing, House Drainage, Registration, and Licensing of Plumbers in the City of Philadelphia, as reported by the Committee of Twenty-one. Philadelphia: P. Blakiston, Son & Co., 1883. Pp. 14. [Price, 10c.]

Microscopical Examination of Potable Waters in the State of Connecticut. By William J. Lewis, M. D. Pp. 20. [Reprint from the "Proceedings of the State Board of Health," 1883.]

Review of the Drug Trade of New York, for the year 1882. Prepared by D. C. Robbins, Esq., for the Twenty-fifth Annual Report of the Chamber of Commerce of the State of New York.

Medical Economy during the Middle Ages: A Contribution to the History of European Morals, from the Time of the Roman Empire to the Close of the Fourteenth Century. By George F. Fort, author of the "Early History and Antiquities of Freemasonry." New York: J. W. Bouton, 1883. Pp. xii-488.

Therapeutic Hand-book of the United States Pharmacopœia. Being a Condensed Statement of the Physiological and Toxic Action, Medicinal Value, Methods of Administration, and Doses of the Drugs and Preparations in the latest edition of the United States Pharmacopœia, with some Remarks on Unofficial Preparations. By Robert T. Edes, M. D., Fellow of the Massachusetts Medical Society, etc. New York: William Wood & Co., 1883. Pp. vi-397.

FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 21, 1883.

THE DINNER TO DR. OLIVER WENDELL HOLMES.

At the dinner given to Professor Oliver Wendell Holmes on Thursday night, the 12th inst., at Delmonico's, upward of two hundred gentlemen were present, all physicians, except a few of the invited guests. Dr. Fordyce Barker presided, with Dr. Holmes, the Hon. William M. Evarts, Dr. John T. Metcalfe, Mr. George William Curtis, Dr. S. O. Van der Poel, Dr. J. S. Billings, of the army, Dr. Lewis A. Sayre, Dr. Thomas Addis Emmet, and Dr. Alfred C. Post on his right, and the Right Reverend the Bishop of Rhode Island, Mr. Whitelaw Reid, of the "Tribune," Dr. John C. Dalton, Dr. S. Weir Mitchell, of Philadelphia, Dr. T. Gaillard Thomas, Dr. William Detmold, Dr. Thomas M. Markoe, Dr. James Anderson, and Dr. Isaac E. Taylor on his left. In addition to those who represented the medical profession of the city, a few physicians from out of town were present, among them Dr. James R. Chadwick, of Boston; Dr. John O. Roe, of Rochester; Dr. John B. Roberts and Dr. J. V. Shoemaker, of Philadelphia; Dr. George L. Porter, of Bridgeport, Conn.; Dr. C. M. Carleton, of Norwich, Conn.; and Dr. W. A. M. Wainwright, of Hartford, Conn. Dr. Henry D. Noyes acted as toast-master.

Dr. Barker extended a brief greeting to the guest of the evening, and then called upon Dr. Andrew H. Smith, who gave a supplementary greeting in the form of the following verses:

You've heard of the deacon's one-hoss shay
Which, finished in Boston the self-same day
That the City of Lisbon went to pot,
Did a century's service, and then was not.
But the record's at fault which says that it bust
Into simply a heap of amorphous dust;
For, after the wreck of that wonderful tub,
Out of the ruins they saved a hub;
And the hub has since stood for Boston town,
Hub of the Universe—note that down.
But an orderly hub, as all will own,
Must have something central to turn upon,
And, rubber-cushioned, and true, and bright,
We have the axle here to-night.
Thrice welcome, then, to our festal board
The doctor-poet, so doubly stored
With science as well as with native wit;
Pocula nascitur, you know, *non fit*.
Skilled to dissect with knife or pen,
His subjects dead or living men;
With thoughts sublime on every page
To swell the veins with virtuous rage,
Or with a syringe to inject them
With sublimate to disinfect them;
To show with demonstrator's art
The complex chambers of the heart,
Or, armed with a diviner skill,
To make it pulsate at his will;

With generous verse to celebrate

The loaves and fishes of some giver,
And then proceed to demonstrate

The lobes and fissures of the liver;
To soothe the pulses of the brain
With poetry's enchanting strain,
Or to describe to class uproarious
Pes hippocampi accessorius;
To nerve with fervor of appeal
The sluggish muscles into steel,
Or, pulling their attachments, show
Whence they arise and where they go;
To fire the eye by wit consummate,
Or draw the aqueous humor from it;
In times of peril give the tone
To public feeling called backbone,
Or to discuss that question solemn,
The muscles of the spinal column.
And now I close my artless ditty
As per agreement with committee,
And, making place for those more able,
I leave the subject on the table.

Yet one word more. I've had my pride
As *medicus* most sorely tried,
When Englishmen, who sometimes show
Of things American, you know,
An ignorance that is melancholy,
As Dr. Holmes is very jolly,
Assume that he must therefore be
A Doctor of Divinity.
So to avoid all chance of wrong
To medicine, or church, or song,
Let Doctor Holmes discarded be
For Oliver Wendell Holmes, M. D.

And now, for I really must come to an end,
May the fate of the chaise be the fate of our friend.
May he never break down, and never wear out,
But a century old, or thereabout,
Not feeling the weight of the years as they fly,
Simply stop living when ready to die.

In response to the toast, "Our guest," Dr. Holmes read the following:

Have I deserved your kindness? Nay, my friends,
While the fair banquet its illusion lends
Let me believe it, though the blood may rush
And to my cheek recall the maiden blush
That o'er it flamed with momentary blaze
When first I heard the honeyed words of praise,
Let me believe it while the roses wear
Their bloom unwithering in the heated air;
Too soon, too soon, their glowing leaves must fall,
The laughing echoes leave the silent hall,
Joy drop his garland, turn his empty cup,
And weary labor take his burden up—
How weighs that burden they can tell alone
Whose dial marks no moment as their own.

Am I your creditor? Too well I know
How friendship pays the debt it does not owe,
Shapes a poor semblance fondly to its mind,
Adds all the virtues that it fails to find,
Adorns with graces to its heart's content,
Borrows from love what nature never lent,
Till what with balo, jewels, gilding, paint,
The veriest sinner deems himself a saint.
Thus while you pay these honors as my due,
I owe my value's larger part to you,

And in the tribute of the hour I see
Not what I am, but what I ought to be.

Friends of the Muse, to you of right belong
The first staid footsteps of my square-toed song;
Full well I know the strong heroic line
Has lost its fashion since I made it mine;
But there are tricks old singers will not learn,
And this grave measure still must serve my turn.
So the old bird resumes the self-same note
His first young summer wakened in his throat;
The self-same tune the old canary sings,
And all unchanged the bobolink's carol rings;
When the tired songsters of the day are still
The thrush repeats his long-remembered trill;
Age alters not the crow's persistent caw,
The Yankee's "Haw," the stammering Briton's "Haw";
And so the hand that takes the lyre for you
Plays the old tune on strings that once were new.
Nor let the rhymester of the hour decide
The straight-backed measure with its stately stride;
It gave the mighty voice of Dryden scope;
It sheathed the steel-bright epigrams of Pope;
In Goldsmith's verse it learned a sweeter strain;
Byron and Campbell wore its clanking chain;
I smile to listen while the critic's scorn
Flouts the proud purple kings have nobly worn;
Bid each new rhymers try his dainty skill
And mold his frozen phrases as he will;
We thank the artist for his neat device;
The shape is pleasing, though the stuff is ice.

Fashions will change—the new costume allures,
Unfading still the better type endures;
While the slashed doublet of the cavalier
Gave the old knight the pomp of chivalry,
Our last-hatched dandy with his glass and stick
Recalls the semblance of a new-born chick
(To match the model he is aiming at
He ought to wear an egg-shell for a hat);
Which of these objects would a painter choose,
And which Velasquez or Van Dyke refuse?

When your kind summons reached my calm retreat,
Who are the friends, I questioned, I shall meet?
Some in young manhood shivering with desire
To feel the genial warmth of fortune's fire—
Each with his bellows ready in his hand
To puff the flame just waiting to be fanned;
Some heads half-silvered, some with snow-white hair—
A crown ungarnished glistening here and there,
The mimic moonlight gleaming on the scalps
As evening's Empress lights the shining Alps.
But count the crowds that throng your festal scenes,
How few that knew the century in its teens!

Save for the lingering handful fate befriends,
Life's busy day the Sabbath decade ends;
When that is over, how with what remains
Of nature's outfit, muscle, nerve, and brains?

Were this a pulpit I should doubtless preach,
Were this a platform I should gravely teach,
But to no solemn duties I pretend
In my vocation at the table's end,
So as my answer let me tell instead
What Landlord Porter—rest his soul!—once said.

A feast it was that none might scorn to share;
Cambridge and Concord's demigods were there—
"And who were they?" You know as well as I
The stars long glittering in our Eastern sky—

The names that blazon our provincial scroll
Ring round the world with Britain's drumbeat roll!

Good was the dinner, better was the talk;
Some whispered, devious was the homeward walk;
The story came from some reporting spy—
They lie, those fellows—oh, how they lie!
Not ours those foot-prints in the new-fallen snow—
Poets and sages never zigzagged so!

Now, Landlord Porter, grave, concise, severe,
Master, nay, Monarch, in his proper sphere,
Though to belles-lettres he pretended not,
Lived close to Harvard, so knew what was what,
And, having bards, philosophers, and such,
To eat his dinner, put the finest touch
His art could teach, those learned mouths to fill
With the best proofs of gustatory skill.
And, finding wisdom plenty at his board,
Wit, science, learning, all his guests had stored,
By way of contrast ventured to produce,
To please their palates, an inviting goose.

Better it were the company should starve
Than hands unskilled that goose attempt to carve;
None but the master-artist shall assail
The bird that turns the mightiest surgeon pale.

One voice arises from the banquet hall—
The landlord answers to the pleading call;
Of stature tall, sublime of port he stands,
His blade and trident gleaming in his hands.
Beneath his glance the strong-knit joints relax
As the weak knees before the headsmen's axe,
And Landlord Porter lifts his glittering knife
As some stout warrior armed for bloody strife;
All eyes are on him; some in whispers ask
What man is he who dares this dangerous task?
When, lo! the triumph of consummate art,
With scarce a touch the creature drops apart!
As when the baby in his nurse's lap
Spills on the carpet a dissected map.

Then the calm sage, the monarch of the lyre,
Critics and men of science all admire,
And one whose wisdom I will not impeach,
Lively, not churlish, somewhat free of speech,
Speaks thus: "Say, master, what of worth is left
In birds like this, of breast and legs bereft?"
And Landlord Porter, with uplifted eyes,
Smiles on the simple querist, and replies:
"When from a goose you've taken legs and breast,
Wipe lips, thank God, and leave the poor the rest!"

Kind friends, sweet friends, I hold it hardly fair
With that same bird your minstrel to compare,
Yet in a certain likeness we agree,
No wrong to him and no offense to me;
I take him, for the moral he has lent,
My partner—to a limited extent.

When the stern landlord whom we all obey
Has carved from life its seventh great slice away,
Is the poor fragment left in blank collapse
A pauper remnant of unvalued scraps?

I care not much what Solomon has said,
Before his time to nobler pleasures dead;
Poor man! he needed half a hundred lives
With such a babbling wilderness of wires!
But is there nothing that may well employ
Life's winter months—no sunny hour of joy?

While o'er the fields the howling tempests rage,
The prisoned linnet warbles in its cage;
When chill November through the forest blows,
The greenhouse shelters the untroubled rose,
Round the high trellis creeping tendrils twine,
And the ripe clusters fill with blameless wine;
We make the vine forget the winter's cold,
But how shall age forget its growing old?

Though doing right is better than deceit,
Time is a trickster it is fair to cheat;
The honest watches ticking in your fobs
Tell every minute how the rascal robs.
To clip his forelock and his scythe to hide,
To lay his hour-glass gently on its side,
To slip the cards he marked upon the shelf
And deal him others you have marked yourself,
If not a virtue, can not be a sin,
For the old rogue is sure at last to win.

What does he leave when life is well-nigh spent
To lap its evening in a calm content?
Art, letters, science, these at least befriend
Our day's brief remnant to its peaceful end—
Peaceful for him who shows the setting sun
A record worthy of his Lord's Well done!

When he, the Master whom I will not name,
Known to our calling, not unknown to fame,
At life's extremest verge half conscious lay,
Helpless and sightless, dying day by day,
His brain, so long with varied wisdom fraught,
Filled with the broken enginery of thought,
A fitting vision often would illumine
His darkened world, and cheer its deepening gloom,
A sunbeam struggling through the long eclipse,
And smiles of pleasure play around his lips.
He loved the art that shapes the dome and spire;
The Roman's page, the ring of Byron's lyre,
And oft when fitful memory would return
To find some fragment in her broken urn,
Would wake to life some long forgotten hour,
And lead his thought to Pisa's terraced tower,
Or trace in light before his rayless eye
The dome-crowned Pantheon printed on the sky;
Then, while the view his ravished soul absorbs
And lends a glitter to the sightless orbs,
The patient watcher feels the stillness stirred
By the faint murmur of some classic word,
Or the long roll of Harold's lofty rhyme,
"Simple, erect, severe, austere, sublime!"—
Such were the dreams that soothed his couch of pain,
The sweet nepenthe of the worn-out brain.

Brothers in art, who live for others' needs
In duty's bondage, mercy's gracious deeds,
Of all who toil beneath the circling sun
Whose evening rest than yours more fairly won?
Though many a cloud your struggling morn obscures,
What sunset brings a brighter sky than yours?

I, who your labors for a while have shared,
New tasks have sought, with new companions fared,
For Nature's servant far too often seen
A loiterer by the waves of Hippocrene;
Yet round the earlier friendship twines the new,
My footsteps wander, but my heart is true,
Nor e'er forgets the living or the dead
Who trod with me the paths where science led.

How can I tell you, O my loving friends!
What light, what warmth your joyous welcome lends

To life's late hour? Alas! my song is sung,
Its fading accents falter on my tongue.
Sweet friends, if, shrinking in the banquet's blaze,
Your blushing guest must face the breath of praise,
Speak not too well of one who scarce will know
Himself transfigured in its roseate glow;
Say kindly of him what is, chiefly, true,
Remembering always he belongs to you;
Deal with him as a truant, if you will,
But claim him, keep him, call him brother still!

Bishop Clark spoke to the toast, "The Clergy," Mr. Evarts to "The Bar," Dr. Thomas to "The Medical Profession," Mr. Curtis to "Literature," and Mr. Reid to "The Press." The speeches made by all these gentlemen were exceptionally happy, and the occasion was in every way enjoyable.

At the conclusion of Mr. Reid's speech, Dr. Barker said: "We have not had time to read the letters of regret from our invited guests and subscribers, who have been prevented from being with us either by reason of death of some relative, personal illness, or other causes beyond their control. I must mention the names of Dr. S. D. Gross and Dr. William Pepper, of Philadelphia, Dr. Henry J. Bigelow, of Boston, and Dr. Willard Parker, Dr. Alonzo Clark, Dr. Austin Flint, Dr. William H. Draper, Dr. Austin Flint, Jr., and others whose names at the moment I do not recall, and Dr. John P. Gray, of Utica. I now propose as a final toast, 'Absent Friends'—those of our brethren who have not been able to join in the present happy reunion—to be drunk standing, and I shall ask Dr. W. T. Bull to lead off in singing 'Auld Lang Syne' as a response and a benediction."

THE LEGISLATURE AND THE UNITED STATES MEDICAL COLLEGE.

THE bill to legalize the incorporation of the United States Medical College, and the diplomas granted by it, by act of the Legislature, to which we referred in our issue of the 7th instant, has been so far successful as to pass the Assembly. The bill does not seem to have been scrutinized at all, but to have been passed without a single member attempting to inform himself of the propriety of such an act. The text of the bill is as follows:

"All scientific, medical, and literary colleges and universities, and all associations of five persons or more, a majority being citizens and residents of this State, which have filed their several certificates with the intention of organizing or incorporating under said acts a scientific, medical, or literary college or university, and which have reported to said regents within the two years last past, are hereby declared to be and to have been legally incorporated upon the filing of their several certificates, for the purposes set forth therein, and with all the rights, powers, and authority incident to and possessed by corporations duly organized for such purposes; and all by-laws heretofore made by such colleges, universities, or associations, all elections held and all degrees and diplomas conferred, and all the official acts and proceedings of the trustees named in such certificates and of their successors, incident to said purposes since the filing of said certificates, are hereby ratified and confirmed, and all

rights arising therefrom are hereby secured and perpetuated; and all such colleges and universities shall be subject to the same duties, liabilities, and obligations, and to the same control and visitations of said regents as colleges and universities chartered by said regents."

This bill is a pernicious one in many respects, and ought in some way to be killed. It not only attempts covertly to bolster up a miserable institution which has been a reproach and disgrace to the medical profession, but it goes to the astonishing length of actually legalizing whatever may have been done under the guise of a college by any association of five persons. It does not seem possible that it could have been understood how sweeping were the clauses of this remarkable bill. No respectable college needs the help of any such law, and none other ought to have it. Another very serious objection to the bill is, that it would practically nullify a judgment of the Supreme Court, even while that judgment stands in full force and un-reversed. If injustice has been done the United States Medical College, it can be set right by an appeal from the decision; if no injustice has been done, the judgment ought to stand unaffected by any act of the Legislature. It is a vicious mode of procedure, and one calculated to bring disgrace upon the courts, to allow a judgment to be set aside by legislative power.

CLINICAL INSTRUCTION IN NEW YORK.

If it be truth, as a correspondent of a prominent British medical journal wrote a year ago, that it is possible to be graduated from a regular medical college in the United States without ever having "seen a case," it is a very exceptional truth. The real progress which has been made in medical education in America—and it can not be denied in the light of recent events that great and creditable progress has been effected—has been almost solely in the direction of clinical medicine and surgery. All medical schools which make any pretensions to excellence in teaching, and those which attract the largest bodies of medical students, emphasize the necessity and profess to have the means for clinical teaching. From this necessity for clinical material, which is now generally recognized, come the decline of the once popular and flourishing country schools and the rise of the great colleges in the leading and populous cities; and it may be safely asserted that the future of medical education belongs to the crowded cities, where wealth and poverty dwell side by side, where the poor are so poor that they are glad to accept the charity of the medical profession at the risk of personal annoyance in being used for purposes of clinical instruction, and the rich so rich that money flows without stint from full hands into the treasuries of the great medical charities.

On account of its geographical position, immense population, and great wealth, New York has become the medical as well as the commercial metropolis. Two millions and a half of human beings dwell within sight of its observatories; and how much this resident population is increased by visitors can not be readily estimated. Twenty thousand ships annually discharge their cargoes at its docks, and the crowd brought by the many railroads must swell the total by hundreds of thousands. From this contact of so many beings crowded together in a limited territory come the accidents and diseases which make medical charities among the first necessities of city life. How great this necessity is, and how generously it is responded to by the charitable, the following list of eleemosynary institutions will show. In so far as could be obtained from official sources,

the number of persons treated for sickness or injury and the amount of money expended annually in the support of this vast clinical material is stated. When not otherwise given, the reports of the year 1881 are copied from:

• November, 1882, to April, 1883.

The number of patients, as given in the reports of these institutions for one year (and, as the reports for 1882 are not yet published, those of 1881 are chiefly used), is 369,577. In some of the smaller charities the number of patients is not given, and, in about one half of all, the amount of money expended is not reported. There is, however, a fairly reliable basis of calculation, for in those institutions in the reports of which the number of patients and amounts of expenditure are given there is an annual outlay of \$852,386 for the medical care of 275,202 patients. This would make the yearly expenditure in the support of medical and surgical charities in New York city \$1,135,511.

Properly organized and judiciously managed, what immense benefit the medical profession might gain from the utilization of this vast clinical material! And yet what a small proportion of the large number of medical students and practitioners who visit the city have heretofore realized a satisfactory use of it. There are but about seventy annual vacancies in the institution

assistant staffs in the city hospitals, and candidates are willing to spend from six months to one year in special preparation for these positions. As to the dispensary appointments, they fall naturally to the younger members of the profession who reside and practice in the city, while the physician from a distance, equally anxious to acquire proficiency in general or special medicine, must rely upon the overcrowded clinical lectures for practical instruction.

The unsatisfactory result of this method of clinical teaching has long been recognized, and the solution of the difficulty lies, we think, in sectional clinical instruction—that is, practical lessons to small classes by experienced teachers, where each member of the class may thoroughly and personally examine and study each case at leisure, and ask questions of his instructor without embarrassment. The success of the New York Polyclinic is a practical demonstration both of the necessity felt by practitioners for more thorough clinical knowledge and of the practicability of organizing and controlling a large and select clinic by judicious management. Here there is an actual working force of fifty-three teachers and assistants, and an average of eight hundred patients are treated every month in the presence of the various sections of the class. By reason of the connection of the Polyclinic staff with other charities, and by the wise and liberal action of the governing boards of these institutions in leaving to the discretion of the medical staff the use of the material provided for by them for purposes of practical instruction, a number of the hospitals mentioned above contribute to the completeness of the organization—namely, Bellevue Hospital, Charity Hospital, Mount Sinai Hospital, the German Hospital, St. Francis's Hospital, St. Elizabeth's Hospital, the Woman's Hospital, the New York Eye and Ear Infirmary, the Manhattan Eye and Ear Hospital, the Maternity Hospital, and other hospitals and dispensaries.

Such an amount of clinical material has never heretofore been organized and concentrated here for the purpose of teaching general or special clinical medicine to practitioners, and, if the judicious management, harmonious co-operation and energy which have gained already for this new undertaking in the direction of higher medical education are continued, the success of the movement will be permanent and complete.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

A STATED meeting was held February 27, 1883, T. M. MARKOE, M. D., President, in the chair.

ABCESS IN THE LOWER PART OF THE FEMUR.—Dr. F. LANGE presented a patient, twenty-eight years of age, who had bone abscess. When thirteen years of age he was subject to osteitic affection of the femur, and during the next six years suffered from repeated exacerbations of the disease. The disease commenced with very severe pain, which lasted for one year; but not until the end of two years did a sinus open, and some pieces of bone make their exit. At the end of six years, no operation ever having been performed, all the sinuses closed, and the patient remained apparently well until last August, when he again began to suffer from severe pains without apparent cause, especially at night; and when Dr. Lange saw him, in the beginning of October, he was very much reduced in strength, and presented that exhausted appearance and pale gray complexion ordinarily seen with chronic bone abscess. On examination, the femur was found very much thickened in its lower half, and

somewhat thickened higher up. There was pain upon deep pressure in the region between the middle and the lower third of the thigh. The entire history of the case made it probable that central abscess of the bone existed, and he therefore, early in October, laid bare the bone, and bored into it in two places without finding pus; but, on making a third opening, pus discharged, and he then enlarged the opening and found quite an extensive abscess, the cavity of which seemed to be very narrow and made up of several lacunæ, one of which contained a small sequestrum. About half of the femur had to be chiseled open, the thickness of the wall of the abscess reaching in some spots nearly an inch. The immediate surrounding of the pus cavity consisted of soft cancellous tissue, pervaded by granulations and small pus cavities. But over that was a very thick sclerotic bone substance. After the abscess had been evacuated and scraped out, the soft parts were closely stitched together by *étage* sutures, two bone drainage-tubes were inserted, and permanent antiseptic dressings were applied. During the next six weeks only four dressings were applied, and no accident took place, except necrosis of the superficial fascia in the upper part of the wound, and there still remained some small openings, which were simply superficial, and had no connection whatever with the cavity of the bone. The femur upon the affected side was about an inch and a third longer than the other. Furthermore, the position of the knee was that of over-extension, and at the same time there was a slight amount of mobility in the joint, greatly to the discomfort of the patient, because it caused him a feeling of uncertainty in stepping. To remedy this, to a certain extent, Dr. Lange had advised that an apparatus be worn which should fix the knee. During the past week pain had occurred again, but it differed entirely in character from that from which the patient first suffered, and was shooting up and down the anterior aspect of the thigh. This pain had been relieved by the administration of quinine, and, besides, the patient had a swollen spleen. At the time of the operation, Dr. Lange opened the cavity of the knee joint, which he found obliterated, but no unfavorable symptoms followed. An especially interesting feature in the case was the smooth healing of the bone cavity that followed complete sewing up of the soft parts, with the after-treatment adopted. The scar showed no depression, and was narrow, the greater part of the wound having healed by first intention.

OSTEOMYELITIS OF THE ILIUM.—Dr. LANGE also presented a patient, sixteen years of age, whom he saw for the first time two years ago, and four weeks after the beginning of a severe illness, with the formation of a large abscess on the anterior aspect of the iliac fossa. The hip joint was apparently not involved. He saw the patient in consultation with Dr. Hoelger, of this city, and made a number of incisions for the evacuation of pus. The case illustrated that spontaneous separation of the epiphyseal junction might occur suddenly, as in the next following weeks the patient's limb suddenly showed the deformity characteristic of fracture of the neck of the femur. A weight and pulley was then applied, and the great shortening which had occurred was, for the greater part, removed. Six months after the beginning of the abscess, Dr. Lange performed necrotomy of the ilium, and removed twelve pieces of bone, mostly superficial, some of them central, especially in the upper part of the acetabulum. The patient made a comparatively speedy recovery. The position of the limb remained unsatisfactory—namely, in very great adduction. There was not complete ankylosis. The weight and pulley was applied, and the limb brought down so that the difference in length between it and its fellow was not quite one inch, and, with a corresponding elevation of the heel of the shoe on the affected side, the patient was able to walk very well. Since that time the adduction had relapsed, and Dr.

Lange thought it would be best to let it go on, and, after complete ankylosis had taken place, to make section of the bone for the correction of the deformity. He had had three cases of acute osteomyelitis of the ilium, in two of which there was separation of the epiphyseal junction at the neck of the femur. In one case he took particular care to avoid separation by applying a weight and pulley, and yet the accident occurred.

EXTIRPATION OF THE LOWER PART OF THE RECTUM, AND ALSO THE COECYX.—Dr. LANGE also presented a patient from whom he had removed the lower part of the rectum for cancer, and, to facilitate the operation, he had also removed the coecyx. The patient had been operated upon twice, the second time for recurring disease within the pelvis in the depth of the ischio-rectal fossa. At the present time he had several suspicious glands in the inguinal region. He presented the patient to illustrate the comparatively good functional result which followed the operation—namely, he was able to control the discharges from the bowels perfectly, if the passages were consistent. Flatus escaped, however, without the control of the patient. The first operation was performed one year ago; the second operation was performed last October. The coecyx was removed at the first operation. At the second operation he removed the mucous membrane to some extent, on account of prolapsus. The removal of the coecyx at the first operation facilitated operative measures very much. There was not much obstruction of the bowel before the first operation was performed. The patient was not aware of the existence of the disease until about six weeks previously, and yet he had extensive disease of the rectum. He had supposed that he was the subject of hæmorrhoids, and had been treated for that affection. The explanation which Dr. Lange gave of the ability of the patient to control the discharges from the bowels was that the sphincter tertius had maintained its function. It could be felt as a weak and soft, somewhat incomplete, closure, immediately above the new external opening.

Dr. L. A. STIMSON remarked that Dr. Lange's first case illustrated the importance of early attention to purulent disease within bone. He recalled a case in which he trephined the head of the tibia in a patient fourteen or fifteen years of age, who had been suffering for eighteen months with recurrent attacks of pain in the shaft of the tibia, and thickening of the upper and middle thirds of the bone had developed. He localized the seat of maximum pain and trephined at that point, and pus was found in the medullary cavity after passing through a layer of compact bone one fourth of an inch in thickness, and the operation was followed by rapid recovery, which had remained permanent to this date, nearly three years. At the time of the operation there was no sinus or discharge of pus, but the bone appeared somewhat thickened and was sensitive, and the soft parts lying over it were thickened. On reaching the bone, the periosteum was found thickened, and an abscess opened which contained from half an ounce to an ounce of pus.

Dr. POST remarked that in cases of persistent pain in the tibia, confined to a limited space, a diagnosis of abscess was a pretty safe one to make.

THE USE OF LIGATURES IN THE WOUNDS OF VEINS.—Dr. L. S. PILCHER then read the following paper:

Dr. Benjamin Travers, in his essay on "Wounds and Ligatures of Veins," which was published in 1811, seems to have been the first to draw special attention to the dangers attending injuries of veins. He speaks of the "fatal catalogue of tied veins," and says that he has observed something like that superstitious alarm which is excited by events that we do not expect and can not explain when such a catalogue is compared with the generally successful cases of tied arteries.

Mr. Travers says that it has been shown "that the inflam-

mation of the interior tunic of a vein sometimes follows a puncture, sometimes a division, a ligature encircling the tube, or including only a part of it; or arises spontaneously from an inflamed surface, of which the vein forms a part."

He ascribes to John Hunter the credit of having first distinctly pointed out the liability of the interior tunic of veins to inflammation, and exclaims that it is most extraordinary "that this alarming and often fatal inflammation of the inner coat of veins should so long have escaped the notice of the profession."

The language of Mr. Hunter (quoted by Mr. Travers from the "Medical and Chirurgical Transactions," vol. i, pp. 18, 19) is: "I have found in all violent inflammations of the cellular membrane, whether spontaneous or in consequence of accident, as in compound fracture, or of surgical operation, as in the wound of an extremity, the coats of the larger veins passing through the inflamed part become also considerably inflamed, and that their inner surfaces take on the adhesive, suppurative, and ulcerative inflammations; for in such inflammations I have found in many places of the veins adhesion, in others matter, and in others ulceration." "I have found them" (these appearances) "in the bodies of those who have died from amputations, compound fractures, and mortifications."

Mr. Travers, in this essay, remarked the indisposition to inflame manifested by the inner tunic of veins as a rule, having himself observed that, even after ligation, there was no blush upon the inner tunic, much less any sign of adhesive inflammation, or thickening of the proper coats of the vein, or agglutination of the contiguous folds (p. 201), so that the processes of healing and of division by ulceration seem to him to be conducted without any manifest sign of inflammatory action in the interior tunic. He thought, however, that this was not inconsistent with a liability to inordinate and excessive inflammation under adequate excitement.

This opinion as to the indisposition of the inner tunic to inflame has become more positively expressed by recent writers. Nicaise, in his thesis, "On Wounds and on Ligation of Veins" (Paris, 1872), p. 74, states that, though Hunter and, after him, Ribes, Gendrín, and others, considered phlebitis as an inflammation of the internal tunic, numerous observations since their time have demonstrated that primary inflammation of that membrane is very rare, if, indeed, it exists. He does not enter into any discussion of the subject, but contents himself with saying that most frequently inflammation begins in the cellular tunic, and thence may spread to the middle and involve also the internal tunic. He quotes Trousseau and Rigot (from the "Arch. gén. de méd.," 1827), as saying that "every year we see patients succumb to phlebitis supervening upon phlebotomy. We are far from denying the frequency of the accidents which follow bleeding; but too often there has been taken for an inflammation of the vein what was only inflammation of its cellular sheath," a kind of periphlebitis being the real malady. Still more positively does Mr. Callender, in the article on diseases of veins, in Holmes's "System of Surgery," claim that primary inflammation of the inner tunic of veins is never met with, and that in all cases we have to do with either progressive coagulation of blood within veins, and its sequelæ, or with diffuse phlegmonous inflammation of their connective-tissue sheaths, thromballosis and periphlebitis being thus substituted in surgical nomenclature for phlebitis. Diffuse periphlebitis, according to this author, can not occur in a patient in a fair condition of health, and, when it does occur, after puncture or division of a vein, it is not a consequence of the application of a ligature; for, whether the vessel be tied or not, this inflammation may supervene.

The change of views which appears, from these brief historical references, to have taken place as to the liabilities to

inflammation inherent in veins has been attended with corresponding changes in the character of the surgical interference to which they are subjected. To a period during which there was entire absence of apprehension of danger, so that, to use the language of Travers, they were attacked with singular rudeness—pricking, cutting, tying, and burning them, without ever adverting to any other than the mechanical effects of such operations upon the diseases for which they were instituted—there succeeded years during which they came to be considered as especially intolerant of interference and prone to the development of unexpected and uncontrollable complications. To this has now succeeded another period in which any special vulnerability in veins is not admitted and a tendency to return to unrestricted attacks is manifest.

For the purpose of eliciting the experience and opinions of the surgeons of to-day on the important question of the hazards of surgical interference with veins, I took up, one year ago, in a paper which I read before the Philadelphia County Medical Society, the subject of the ligation of large venous trunks. It will be remembered that Dr. S. W. Gross, of Philadelphia, in a paper published by him in the "American Journal of the Medical Sciences," in 1867, upon "Wounds of the Internal Jugular Vein and their Treatment," reached the conclusion that the dangers of ligation of that vessel had been greatly exaggerated, as not a single example had been found by him in which ligation had been followed by diffused phlebitis. Embodied in that paper was also a summary of the teachings of prominent surgical authors of the present century up to that date as to venous ligation in general, from which it appears that while a numerical majority teach that its risks have been greatly exaggerated, yet a sufficiently large number, including the names of Roux, Lisfranc, Langenbeck, Miller, Erichsen, and Pirogoff speak of it as being attended with great danger, and to be avoided by all possible means.

I called attention, also, to the additional source of danger which had been claimed to exist in the denudation and contusion of veins. Dr. Gross, in his paper, had quoted the observations of Broca, who, in his treatise on aneurysms ("Des anévrysmes et de leur traitement," p. 478, Paris, 1856), describes inflammation of the accompanying vein, denuded, perhaps bruised in exposing an artery for the purposes of ligation, as one of the possible complications of such operations; also, two cases reported by Langenbeck (in "Archiv für klinische Chirurgie," 1860, t. i), with a fatal result in one of the cases, in which thrombosis followed, a denudation of veins occurring in the course of the removal of tumors; also observations of a similar nature by Post and J. C. Warren.

Nicaise, in his thesis already referred to, quotes these observations also, and adds that Ollier, of Lyons, has several times observed this accident, so that he has formed the opinion that extensive denudation of a large vein is more dangerous than ligation, and that, where after such denudation immediate union is not obtained, when the flaps that cover the veins slough, when, in a word, the veins remain exposed at the bottom of the wound, all the accidents of an extensive and progressive thrombosis are likely to occur. In three instances Ollier had seen death follow in from eighteen to thirty-six hours after the beginning of the thrombosis. Happily, however, says Nicaise, denudation does not inevitably involve accidents so grave as those noted by Ollier. Most frequently it is followed by no complication. Nicaise also quotes the opinion of Weber (Pitha und Billroth, "Handbuch der allgemeinen und speciellen Chirurgie"), that contusions of veins are more likely to be followed by thrombosis and suppurative periphlebitis than are pricks and lateral wounds.

(To be concluded.)

Reports on the Progress of Medicine.

QUARTERLY REPORT ON OBSTETRICS AND GYNÆCOLOGY.

No. XXIV.

By ANDREW F. CURRIER, M.D.

THE CÆSAREAN OPERATION.—Beumer ("Arch. f. Gynäk.," xx, 2, 1882) describes an operation performed upon a woman, forty-one years of age, who had enjoyed good health during the most of her life, had borne five children without mishap, and was now pregnant for the sixth time. As the time for labor approached, the midwife who was summoned advised professional assistance, and she was sent to the obstetrical polyclinic at Greifswald, where she came under the observation of the author. The bladder was first evacuated of twenty-five hundred grams of urine. Examination then revealed that the foetal heart sounds were distinguishable, and that the head was presenting. The lengthened vaginal portion of the cervix was drawn well up, behind the symphysis; the os externum was patent; the cervical canal, eight to ten centimetres in length, could be traversed by the finger with difficulty. Through the anterior vaginal wall no presenting foetal part could be felt. Through the posterior wall a tumor about as large as a child's head could be made out, lying well in the superior strait, with barely sufficient space between it and the cervix to pass the fingers. Posteriorly, the fingers could not be passed to the promontory. The tumor seemed to be firmly fixed. The diagnosis was made of an intra-uterine pregnancy at the end of the ninth month, with a fibromyomatous tumor of the posterior wall of the cervix which entirely prevented labor. The case was further complicated by cystitis and suppurative pyelonephritis. Cæsarean section was decided upon, and carried out with strict antiseptic precautions. The abdominal incision was made in the linea alba from a point two centimetres above the navel, passing to the left of the same, and ending at a point four centimetres above the symphysis. The peritoneal section extended as far as the vertex of the bladder. A solid rubber tube of the thickness of the little finger was then passed around the lower segment of the uterus, the intention being to constrict the uterine walls with it as soon as the cavity was opened. The uterus was then opened in its middle line by an incision, eleven centimetres in length, which extended almost to the upper boundary of the lower uterine segment. At the upper end of the incision the placenta was cut, but hæmorrhage was almost immediately stopped by tightening the rubber tube referred to. A living and active female child was quickly extracted by the feet, and the cord was cut and secured. The membranes and the placenta were also removed successfully, and the uterine cavity was then carefully sponged out with a five-per-cent. carbolic solution. The peritonæum was then peeled away from both edges of the wound for a distance of one centimetre, and a wedge-shaped segment of muscular tissue was excised. This permitted the turning in of the excess of peritonæum, which was one centimetre in width. The wedge of muscular tissue removed had its base outward—that is, next the peritonæum; consequently the edges of the wound lay, as to their smaller, external portions, with a peritoneal covering, while within, their larger inner portions were composed of the muscular structure of the uterus. The uterine wound was closed with seven deeply passed sutures, made from English fish-line, which had previously been boiled in a five-per-cent. solution of carbolic acid. The decidua was not included in the suturing. Four superficial sutures were also passed, after which the tube around the uterus was removed. No hæmorrhage followed, and these steps had taken only twenty

minutes. In the *toilette* of the peritoneal cavity a sponge accidentally slipped from the sponge-holder and could not be found until the intestines were removed, when it was discovered in Douglas's pouch. From this point the patient did poorly, though, before the manipulation of the intestines, everything promised favorably. The abdominal wound was hastily closed, and nearly an hour was spent in efforts, which were finally successful, to restore the pulse and breathing to their proper condition. The patient lived only about thirty-six hours after the operation. In defense of his course in adopting the Cesarean section in preference to Porro's operation, the author states that the existence of the large fibroid, which has been already referred to, would have prevented the obtaining a suitable pedicle, and hence the operation (Porro's) could not have been performed. The indications for Porro's operation are the following: 1. Stenosis or atresia of the cervix and vagina, or interference with the parturient canal by a tumor which does not belong to the uterus itself. 2. Pregnancy in the closed half of a bicornate uterus. 3. Infection of the body of the uterus under certain conditions. 4. Cases in which Cesarean section has been repeatedly performed. 5. Marked general osteomalacia. The autopsy revealed the beginning of peritonitis, but nothing else that was attributable to the operation.

THE TREATMENT OF FUNICULAR HERNIA.—Krukenberg (*ibid.*) remarks that the treatment of this accident has not usually been attended with great success. A few cases have been cured spontaneously, a few others have yielded to varying degrees of pressure. Various kinds of operative procedures have been adopted at different times. They are very likely to prove fatal, and are strongly disapproved of by numerous authorities, which are quoted. Kocher, B. Schmidt, and König advise against operation, excepting in cases where there are symptoms of strangulation. In cases of extensive but still reducible hernia, neither reposition and compression, nor yet the modified ligature (that is, a ligature passed around the base of the sac after the hernia has been reduced, or the use of pins or sutures to bring together the divided abdominal walls), will satisfy the demands of modern surgery. The plan which the author adopted in a case which was under his supervision consisted in reposition, opening of the hernial sac, removal of the same, freshening of the edges of the wound, and careful suture of the same with ten silk sutures, in the same manner which is customary in ovariectomy. All was done with strict antiseptic precautions, and the child made a good recovery, though it had been born but fourteen hours at the time the operation was performed. The author seems to think favorably of operative procedures.

THE CAUSE OF HEAD PRESENTATIONS.—Mech (*ibid.*) remarks that, according to the view which is as old as the time of Hippocrates, the breech of the fetus lies lowest in the uterus until the seventh month, when the body is rotated and the head takes that position. This view was disputed in 1559 by Columbus, who held that the head of the fetus was in the pelvic cavity from the beginning. Three hypotheses have been assumed as the cause of the frequency of head presentations: 1. That the force of gravity is the cause. This was assailed by Paul Dubois and by Simpson. 2. The one which was advanced by Simpson, viz., that the cause lies in a kind of reflex movements on the part of the fetus, which are induced by the pressure of the walls of the uterus upon it, until that position is assumed which corresponds most nearly to the shape of the uterine cavity. 3. Kristeller considered (1855) that the cause lay in the activity of the uterus during pregnancy. Each of these theories has its advocates and its opponents, but they are all unsatisfactory, in that they attempt to explain only the change from a breech to a head position, while for the reverse of this, which is of common occurrence, no explanation is attempted. The author next lays down

the principle that the frequency of a fetal position can best be explained in connection with a satisfactory knowledge of the causes by virtue of which it changes its position. That fetal movements are common and frequent is well enough known. They have been carefully studied by Hecker and by Cr  d  , and the results have been published. The muscular organism with which the fetus is furnished, which is highly developed toward the close of pregnancy, when these movements occur, is a sufficient explanation of their occurrence. The four extremities of the fetus are chiefly concerned in its motions, and it is their action which determines the position of the trunk, while the position of the trunk really determines that of the head. The extension of the limbs is far more significant than their flexion as to the movements of the fetus. When one of them is extended, there is either a relaxation on the part of the uterine wall which was touched by it, or that portion of the fetus which is contiguous to the extremity (shoulder or pelvis) changes position. Should neither the uterine wall nor the fetus itself relax, the result would simply be contact of the latter with the former. The parts of the uterus where motion most readily takes place are at the fundus and the sides. The resisting nature of the parts in the region of the superior strait of the pelvis and the sacrum readily show that the vertical position, whether with the head or the breech in advance, favors stability when the limbs are extended more than does either a transverse or an oblique position. When the breech is in advance, it is not difficult to see that when the lower limbs are extended its position is likely to be changed. When the head is in advance, motion of extension on the part of the lower limbs results in contact with the soft tissues of the fundus uteri, above and around which are other soft tissues. Extension of the upper limbs acts upon the parts of the uterus which are above the pelvis. The position of the shoulders may be changed thereby, but the head, which is the end of the longest fetal diameter, is not apt to have its position disturbed, the upper extremities acting rather upon the parts toward the middle of the body than upon the head. Of course, the position is the more stable the farther the head has passed into the entrance to the pelvis. The limbs are usually directed toward the side-walls of the uterus, which are more yielding than the front. Also, there is less resistance upon the right side than there is upon the left, where the descending colon and its contents are located. This accounts for the greater frequency of the first position, whether it be of the head or of the breech, and, indeed, the same holds true for the transverse position. During labor, the extension of the limbs exerts by no means so significant an influence upon the relations of position of the fetus as during pregnancy.

THE SHARP CURETTE IN OBSTETRICS.—Concerning the use of the sharp spoon in obstetric practice, says Von Weeckbecker-Sternefeld (*ibid.*), the hemorrhages and degenerative changes which follow some cases of midwifery require energetic treatment, not only on account of the immediate danger to life, but also on account of the protracted bodily weakness which is entailed by them. [Reference is here made, of course, to the remnant of the products of conception, either in the shape of membranes or placenta, which nature has failed to expel at the time of labor, whether at full term or premature.] For accomplishing this end, either the hand or the finger has been deemed a sufficient means by most writers. The author desires to advocate the use of Simon's sharp spoon for this purpose, and claims as its advantages: 1. A lesser degree of danger of infection from its use than by the use of the finger. 2. The minimum of dilatation is required for its use. 3. The substances which are to be removed can be removed thoroughly with the spoon. 4. Far less pain is produced. 5. Severe irritation of and powerful traction upon the uterus and the entire genital tract are avoided.

The following indications for the use of the sharp spoon are given: 1. In premature parturition during the period encompassed by the first three months of pregnancy, when there is retention of the entire product of conception with hæmorrhages or other serious disturbances, the fœtus and secundines being firmly adherent to the uterus; or when the fœtus and secundines have been released from their uterine attachment, but there is not sufficient dilatation to permit of their expulsion unaided; or when the fœtus has been expelled, but the secundines or a portion of them remains—in all these cases the offending substances must be removed quite as much on account of any trouble which they may cause as for any trouble which they have caused. 2. The retention of portions of the placenta after the delivery of a premature or a full-term fœtus. In such cases we not only are likely to have severe hæmorrhages soon after labor, but also the dangerous forms of puerperal diseases. The use of the sharp spoon is in these instances productive of most positive and satisfactory results. 3. The paring off of the inner surface of the uterus will prove a powerful and harmless irritant, in connection with other agencies, such as the use of ice, in cases of post-partum atony of the uterus, and is worthy of more extensive trial. 4. During the puerperium the spoon may be employed for the removal of clots which have collected in the uterus, together with other débris, being used as an adjunct to irrigations of the uterus, and also for the removal of polypoid growths at the placental site. 5. Such growths as *mola carnea* and *hydatidosa* may also be removed with this instrument. In manipulating the instrument, care must be taken to avoid wounding tissues contiguous to those which are to be removed. Especially must caution be exercised in cases where the uterus is fixed by adhesions. The author thinks it better to perform the operation without an anæsthetic, where this is possible. A table of one hundred cases is given, in which the patients embodied the different conditions which have been referred to as indications for the use of the spoon, and in which, in fact, it was used. [Fewer cases of inflammation followed the operation than we should have anticipated from such treatment.] Only five cases ended fatally, and the author thinks that in only one of these can the issue be attributed to the use of the spoon. The author thinks that the instrument will also be serviceable in some of the destructive operations of midwifery, in which it is desirable to penetrate the fetal body, as in cases of deformity with enlargement of some portion of the body. [If we were to criticise the author's statements, we should begin by expressing doubt as to the propriety of using a sharp spoon or curette in any of the conditions which he has mentioned, the dull wire curette being certainly safer and quite as effective. The paring away of a portion of the uterine mucous membrane (if that is what the author means) would seem to be particularly dangerous, and, in all cases where the spoon is used, a free absorbing surface, with its attendant dangers during the process of uterine involution, will be left.]

THE ÆTIOLOGY OF INVERSION OF THE UTERUS.—FÜRST (*ibid.*, xx, 3) thinks that the important question, in a medico-legal point of view, in regard to the possibility of a spontaneous origin of inversion of the uterus has been answered in different ways, so that it can not be definitely stated how frequently this form occurs in comparison with that which is produced by the action of external force. Too little consideration has been paid to the fact that complete atony, at least of a portion of the uterus, is the chief condition upon which inversion is based, and, this being present, only a slight exercise of force, as by the action of the abdominal bandage, with certain voluntary or involuntary movements added, will result in the accident referred to. The literature of this subject is quite meager, as the accident is comparatively rare. A case which occurred in the au-

thor's experience is narrated, the inversion occurring spontaneously soon after delivery and requiring much effort to accomplish its restoration, which was finally done. The patient was greatly prostrated from loss of blood and of nerve power, but made a good recovery. The patient was a primipara, and the author thinks the accident occurs oftener among primiparae than is generally supposed. The following statements are made concerning this accident: 1. After a protracted labor, which is the more common in primiparae, weakness of the pains may be a cause of inversion, and, if a delivery has been accomplished with the forceps, the liability to the accident is increased. 2. A placenta whose site is at the fundus is a predisposing cause, and occurs more frequently in primiparae, just as placenta prævia is more common among multiparae. 3. The comparatively tense vaginal walls in primiparae hinder inversion, and, if the accident occurs, this condition may assist spontaneous reduction. 4. The narrower vulva in primiparae may prevent the free discharge of blood. With the accumulation of the latter and subsequent pouring out, a force may be exerted which will produce inversion. Pathological growths upon the placenta, adhesions of this organ to the uterus, and adhesion of the membranes, may also act as sufficient causes to produce this accident.

ENDOMETRITIS FUNGOSA.—Under the general name of endometritis fungosa, says Brennecke (*ibid.*), one is accustomed to include a series of morbid phenomena which differ greatly among themselves etiologically and anatomically, but clinically are quite similar. The chief symptom is profuse and continued hæmorrhage, which is naturally followed by decided anæmia. The cervical canal is usually patulous, and upon the mucous membrane of the body of the uterus are new growths, which are not apt to be very large. When these have been removed with the curette, the hæmorrhages cease for a time, or perhaps permanently. Olshausen's brochure, "concerning chronic hyperplastic endometritis of the corpus uteri (endometritis fungosa)," appeared in the year 1875, arranging and explaining the different opinions in regard to this subject. A few years later, Bischoff, re-enforced by clinical and microscopic observations, arranged endometritis fungosa into four anatomically distinct forms, though they have points in common, and can not always be separated. These four forms are, in brief: 1. Fungosities developed from oedematous normal tissue, and peculiar granulation tissue which is very vascular. 2. Those which follow abortion, especially when a portion of the placenta or the membranes have been retained. 3. Diffuse adenoma, which is common among multiparae. 4. Diffuse sarcoma. In the first two forms a thorough curetting is likely to produce a radical cure, in the others the disease often recurs. K. Ruge divides the disease into a glandular and an interstitial form, and believes that there is also a form intermediate between these two. An extended description of six cases of the disease (endometritis fungosa) led the author to the conclusion that the primary source, at least in his cases of the disturbance, consisted in functional derangement of the ovaries, probably with reference to ovulation. His opinion in the matter is summarized as follows: Chronic hyperplastic endometritis is to be considered a true hyperplasia of the uterine mucous membrane. It comes on in consequence of a chronic hyperæmia of the uterine mucous membrane, which is due to the abnormal irritation which is sustained by the nervous reflex apparatus governing the menstrual congestion in the ovaries, these organs being changed either physiologically or pathologically, and, therefore, performing their functions in an abnormal manner. The disease will cease when normal ovulation recurs, this being attended by normal menstrual congestion with physiological regularity. When ovulation ceases, the disease will likewise cease, but it must be remembered that ovulation sometimes continues long after menstruation has failed to

reappear. The author does not think that the disease is likely to develop into carcinoma. In cases where repeated curettings have failed to effect a cure, Battey's operation is indicated. In addition to those cases whose origin is ovarian, there are others in which the fungous growths are entirely of a uterine nature, in which catarrhal inflammation of the uterine mucous membrane is the source of the trouble. The following observations will serve as a means for differential diagnosis: 1. In the uterine form of the disease there occur profuse menorrhagia and chronic metrorrhagia, but never an abnormally delayed menopause, while in the ovarian form the abnormally delayed menopause is almost pathognomonic. 2. The tendency to recurrence is far greater in the ovarian form. 3. In the uterine form the mucous membrane has fewer fungosities than in the ovarian form. 4. Microscopically, the tissue removed consists of simple hyperplasia of the mucous membrane, or granulation tissue with more or less of normal mucous membrane, and in both varieties this result is obtained.

[Lack of space prevents the publication of the bibliographical list appended to Dr. Currier's Report.—EDITOR.]

Letters to the Editor.

NOTE ON CHLORAL HYDRATE AS A VESICANT.

St. Louis, April 7, 1883.

To the Editor of the New York Medical Journal:

Sir: A note by Dr. F. D. Ritter, of Gainesville, Pa., to Dr. T. G. Thomas, in a late number of your valuable journal, commendatory of chloral hydrate as a vesicant, prompts me to remark that this agent is such a violent and excruciatingly painfully vesicant as to render it unfit for use in ordinarily sensitive conditions. In 1877 my assistant physician at the Missouri State Lunatic Asylum, Dr. William Wood, employed chloral hydrate externally for the relief of intercostal neuralgia in his own person, and the effect of the application was to produce the most intense agony. He never wished to try the experiment again, nor have I ever since felt inclined to see it tried on any other person. I relieved Dr. Wood of his chloral agony by repeated applications of wet towels, followed by lard spread on cotton batting.

Dr. Wood's neuralgia was speedily relieved by the chloral, but the systemic shock of the application was too severe to justify the use of the remedy, and would have been greater but for the prompt employment of the wet towels.

There might arise circumstances which would justify the use of this severe remedy where reaction to ordinary counter irritation might be doubtful, but for ordinary vesicant indications and purposes the employment of chloral hydrate would be positively cruel, and not at all in accordance with the golden rule. Respectfully,

C. H. HUGHES.

THE OLD CODE OF ETHICS.

NEW YORK, April 9, 1883.

To the Editor of the New York Medical Journal:

Sir: The following is a copy of a letter recently addressed by me to a partisan of the old code. Thinking that it may apply to others holding views like his, I should be glad of the publicity of your columns:

"The profession may not, indeed, care to know what views either you or myself may entertain on most subjects, but, inasmuch as many of them are just now making up their minds on the question of medical ethics, our views may not be without interest to them, as we are in certain ways representative of views held on either side of the controversy. Since our conversation the other day, I have thought over several of your statements with increasing interest, because I am an advocate of the greatest freedom in all of the affairs of men, while I

believe you to be the advocate of the more intolerant measures of the past.

"Before presenting your views on the ethical question to the reader, I need scarcely remind you that I said I was an advocate of reform as regards the old codes of ethics; that I believed they required important changes to adapt them to the wants of physicians of the present day, however patiently they may have been ordered by physicians in the past. That I was not satisfied with the new code, was admitted, but I greatly preferred it to the old one.

"I was led to believe by your remarks that you (the old-coders) were organizing at the present time with the intention of re-establishing the old order of things in this State, and that, if you were unsuccessful in repealing the new code at the next meeting of the Medical Society of the State of New York, you intended to set up a new State society which would be recognized by the American Medical Association. You would thus not hesitate to commit an act of secession against the legalized authorities of your own State in furtherance of these objects. You were uncompromisingly determined that the old-code ultimatum should be the entire abandonment of their advanced position by the new-code men. Were you unsuccessful in persuading the reformers of the evil of their ways, you propose to excommunicate them—to proscribe them—to ostracize them. You said that you (old-coders) would now avoid professional intercourse with the reformers—would not willingly consult with them, etc.

"We agreed respecting the scientific qualifications that a physician should possess, and that they should all be accorded the widest freedom as regards therapeutical methods. The point at which we diverged is, perhaps, the real question at issue, namely, the *business of earnings*. This matter you (old-coders) would regulate for all; you would not have the doctor's success depend upon his adaptability to his social surroundings, but you would establish trades-union methods, thus holding physicians together by fee bills and rules of conduct, or manners. Let me ask you why a physician should not earn his living as do men in other pursuits? Why should not the public, rather than his colleagues, be arbiters of his success? You lay down rules for his guidance such as persons in no other pursuit could or would submit to and yet attain success.

"These are the patriarchal methods of the olden times, established by the fathers in medicine; they were well adapted to ancient times, when the master imparted the secret knowledge of his own ways to the apprentice, but in these modern days instruction in medicine and the collateral branches is offered to all who have the means to avail themselves of such opportunities; and, moreover, there are no longer any secrets in the healing art, the bestowal of which might intrail the recipient indefinitely. Will not the question of manners in the present state of society settle itself for physicians, as it has already done in other walks of life? Can not a gentleman retain his gentle manners as a physician without the restraining influences of a code—and, by the by, will any code make a rude person well-mannered? It seems to me that the desire on the one hand to enforce a rejected and obnoxious code upon all alike is about as inconsistent as the talk of others who fancy that, because a gentleman requires no code by which to regulate his conduct, all may become gentlemen through the removal of restraining influences. The mistake of both extremists seems to lie in the fact that neither recognize the true state of things—namely, that public recognition must depend on acquirements suited to the public's demands. Dr. Flint is not the admirable gentleman in consultation that many of us have found him to be, because of the code which has of late elicited his good-natured commentaries in the 'New York Medical Journal.' These pleasing essays on professional etiquette are highly creditable to his goodness, but they certainly can not seriously be expected to prevent the violation of the code if restored again; nor does the doctor, I fancy, insist on the strict rules of politeness that he has laid down being accepted by those with whom he consults, for he probably adapts himself to the circumstances, and his well known success must largely depend on the agreeable manner in which this is done. Now, the general practitioner finds it to his interest to adapt himself to the social conditions that surround him, without respect to codes, and, if the consultant does not like his methods, he is not obliged to meet him in consultation.

"Is it not to be plainly seen that this question is now settling itself—at least, is it not so here in the metropolis, and also in the State of New York? Is it not better that practices which have generally been successfully carried on surreptitiously should be openly acknowledged or promptly condemned? Are not the codes which we have hitherto permitted to remain in force ineffective to control men, and, therefore, liable to be regarded as better suited to the convenience of the more daring and insincere constructionist than for the advancement of the tyro, who is disingenuously required to pursue the noble art handicapped, as was the ignominious constructor of brick when required to labor without an adequate supply of straw?

"Those of us who have established our professional reputation need not, perhaps, concern ourselves about these ethical disturbances, which are, after all, made much more prominent than needs be. But one particular act of yours as representing old-code ideas gives cause for apprehension to every young practitioner in the land; I refer to your course in respect to a medical journal, where you ceased to be a subscriber because the editor held views differing from your own on the ethical question. It will not be disputed by any one that you have a right to select whatever medical literature you may require, but you intended in this instance to punish the opponent who had incurred your displeasure. Your bigotry was thus sustained even at the possible sacrifice of your intelligence. But this is a mere bagatelle to your threatened crusade against the reformer, whom you propose to ostracize should he not return to the old paths you are holding for him.

"Entertaining these views, should the defenders of the old *régime* even attain ethical ascendancy, I fear your zeal would know no bounds, but that you would strike at every phase of liberty; you might, I doubt not, consider it heresy for others to wear their garments of a cut not meeting with your approval.

"You frankly admitted that you (old-coders) intended to follow out the methods referred to, even if your action should bring about a division among physicians; that you considered this course both necessary and wise, and that you were, for one, willing to devote both time and money to the cause.

"Now, before nailing your flag of disruption to the mast-head and further proclaiming your anathemas, would it not be well to consider once again the consequences of so foolish a course, and, before it is too late, aid in bringing about a conference among those interested, with a view to securing statutory laws, where any are needed, respecting the intellectual status of physicians of all schools, and leave the matter of ethics to take care of itself?"

SAMUEL SEXTON.

Miscellany.

THE DOCTOR OF THE LAST CENTURY.—In Mr. John B. McMaster's "History of the People of the United States," vol. i, just published by D. Appleton & Co., we find the following account of medical study and practice toward the close of the last century:

"Not less important than the school-master, in the opinion of his townsmen, was the doctor. With the exception of the minister and the judge, he was the most important personage in the district. His professional education would now be thought insufficient to admit him to practice; for there were then but two medical schools in the country, nor were they, by reason of the expense and dangers of traveling, by any means well attended. In general, the medical education of a doctor was such as he could pick up while serving an apprenticeship to some noted practitioner in Boston or New York, during which he combined the duties of a student with many of the menial offices of a servant. He ground the powders, mixed the pills, rode with the doctor on his rounds, held the basin when the patient was bled, helped to adjust plasters, to sew wounds, and ran with vials of medicine from one end of the town to the other. In the moments snatched from duties such as these he swept out the office, cleaned the bottles and jars, wired skeletons, tended the night-bell, and, when a feast was given, stood in the hall to announce the guests.

"It was a white day with such a young man when he enjoyed the

rare good fortune of dissecting a half-putrid arm, or examining a human heart and lungs. So great, indeed, was the difficulty of procuring anatomical subjects, that, even at the medical school which had just been started at Harvard College, a single body was made to do duty for a whole year's course of lectures. It was only by filching from grave-yards or begging the dead bodies of criminals from the Governor that subjects could be obtained.

"Under such circumstances, the doctor's knowledge was derived from personal experience rather than from books, and the amount so obtained bore a direct relation to the sharpness of his powers of observation and the strength of his memory. If he were gifted with a keen observation, a logical mind, and a retentive memory, such a system of education was of the utmost value. For in medicine, as in mechanics, as in engineering, as in every science, in short, where experience and practical skill are of the highest importance, a practical education is most essential. The surgeon who has studied anatomy from a book without ever having dissected a human body, the physician who learns the names and symptoms of diseases from a work on pathology, and the remedies from the *materia medica*, without ever having seen the maladies in active operation and the remedies actually applied, is in a fair way to kill far more patients than he will ever cure. But the value of knowledge obtainable from books alone is on that account not less useful, and by no means to be despised. The student who has read much in his profession is in possession of the results of many centuries of experience derived from the labors of many thousands of men. He is saved from innumerable blunders. He is enabled to begin his career with a knowledge of things which, if left to his own experience to find out, would cost him years of patient waiting and careful observation. The advantages of such a system of study were, however, but sparingly enjoyed by the medical students of the last century, when but few physicians boasted a medical library of fifty volumes.

"His apprenticeship ended, the half-educated lad returned to his native town to assume the practice and to follow in the footsteps of his father. There as years went by he grew in popularity and wealth. His genial face, his engaging manners, his hearty laugh, the twinkle with which he inquired of the blacksmith when the next boy was expected, the sincerity with which he asked after the health of the carpenter's daughter, the interest he took in the family of the poorest laborer, the good nature with which he stopped to chat with the farmhands about the prospect of the corn-crop and the turnip-crop, made him the favorite of the county for miles around. When he rode out, he knew the names and personal history of the occupants of every house he passed. The farmers' lads pulled off their hats, and the girls dropped courtesies to him. Sunshine and rain, daylight and darkness, were alike to him. He would ride ten miles on the darkest night, over the worst of roads, in a pelting storm, to administer a dose of calomel to an old woman, or to attend a child in a fit. He was present at every birth; he attended every burial; he sat with the minister at every death-bed, and put his name with the lawyer to every will.

"But a few of the simplest drugs were then to be found stowed away on the shelves of the village store, among heaps of shoes, Roban hats, balls of twine, packages of seed, and fitches of bacon. The physician was, therefore, compelled to combine the duties both of the doctor and the apothecary. He pounded his own drugs, made his own tinctures, prepared his own infusions, and put up his own prescriptions. His saddle-bag was the only drug-store within forty miles, and there, beside his horn balances and his china mortar, were medicines now gone quite out of fashion, or at most but rarely used. Homœopathy, with its tasteless mixtures and diminutive doses, was unknown, and it is not too much to say that more medicine was then taken every year by the well than is now taken in the same space of time by the sick. Each spring the blood must be purified, the bowels must be purged, the kidneys must be excited, the bile must be moved, and large doses of senna and manna, and loathsome concoctions of rhubarb and molasses, were taken daily. In a thousand ways the practice of medicine has changed since that day, and changed for the better. Remedies now in the medicine-box of every farmer were then utterly unknown. Water was denied the patient tormented with fever, and in its stead he was given small quantities of clam-juice. Mercurial compounds were taken till the lips turned blue and the gums fell away from the teeth. The damsel who fainted was bled pro-

fusely. Cupping and leeching were freely prescribed. The alkaloid quinia was unknown till 1820. The only cure for malarial diseases was powdered cinchona bark; but the amount required to restore the patient was so great, and the supply so small, that the remedy was all but useless. Vaccination was not made known by Jenner till 1798. Inoculation was still held by many to be attended by divine punishment. Small-pox was almost as prevalent as pneumonia now is. The discovery of anæsthesia by the inhalation of ether or chloroform was not given to the world by Morton till 1846. Not one of the many remedies which assuage pain, which destroy disease, which hold in check the most loathsome maladies and the most violent epidemics, was in use. Every few years during the dog-days the yellow fever raged with more violence in the northern cities than it has ever done in this generation in the cities of the far South. Whole streets were depopulated. Every night the dead-cart shot its scores of corpses into the pits of the Potter's Field. Better surgery is now generously given to every laborer injured by the fall of a scaffold than could then have been purchased at any price."

THE MERCANTILE MARINE MEDICAL SERVICE.—As a remedy for the unsatisfactory state of affairs connected with the medical service on board passenger vessels, the Parliamentary Bills Committee of the British Medical Association has addressed a memorial to the President of the British Board of Trade, proposing:

1. That the Board of Trade should obtain powers to take this important branch of the public service under its own immediate direction.

2. That a regularly constituted "Marine Medical Service" should be formed, the members of which would be appointed under the direct supervision of the Board, and would be responsible to it for the efficient performance of their duties.

3. That the conditions of such appointment should be reasonably stringent, in view of the serious and difficult nature of the service required.

4. That the present disabilities with reference to unsuitable accommodation, want of assistance, and inadequate remuneration, should be amended under the direction of the Board; and that the position should be made sufficiently desirable to attract and retain the services of thoroughly competent and experienced medical men.

5. That the duties, responsibilities, status, and uniform of marine medical officers should be distinctly determined, and made constant upon vessels carrying passengers under the supervision of the Board of Trade.

6. That the medical officer should have separate authority in sanitary matters, not involving the safety or general discipline of the ship.

7. That he should be assured of the full protection of the Board in the discharge of his duties, and in all cases of vexatious interference, or unfounded complaint.

8. That his tenure of office should be as permanent as in other public services, and not simply from voyage to voyage, as at present.

9. That the conditions of the service should include promotion, and provision for superannuation or retirement through ill-health.

10. That a junior or assistant surgeon should be carried by every vessel having on board more than six hundred persons; and that suitable arrangements should be made for his accommodation and remuneration.

11. That the medical officers should be required to frequently inspect the inhabited portions of the vessel, and to furnish at the conclusion of each voyage a suitable report upon the hygienic conditions of the voyage, and upon all matters likely to affect the health of the passengers. [Such reports, taken collectively, the committee remark, would be of great value to the public service.]

THE LEGAL STATUS OF UNQUALIFIED PRACTITIONERS.—The courts of the various States differ in their decisions as to the right of a physician to recover for the value of his services when he is not a graduate of a medical college. In Maine, where such a person can not sue his patient, the curious question recently arose in a court, whether a physician who had been injured in an accident by the gross negligence of a third party could allege, as an element of damage, the loss to his practice by his enforced idleness. The defendant maintained that the phy-

sician, not being a graduate of a medical college, could not recover for the value of his services, and, consequently, could not set up any loss of time, etc., in the action for negligence. The court, however, decided that such loss of time, etc., must be considered in giving a verdict, as by the Maine law, though the physician had not received a degree or license, still he was not pursuing a business in violation of law. In New York, where it is against the law for a person to practice medicine without a diploma granted by a medical college, such a person can, nevertheless, recover for his services, if a jury believes them to have been of any value, the penalty for practicing in an irregular manner being fine and imprisonment, and not an inability to sue for services. It would seem, therefore, that where the facts were similar to those in the Maine case a person in this State could recover for an injury, although the ground of recovery would be different in the two States.

CREMATION IN PENNSYLVANIA.—An act has been introduced into the Pennsylvania Legislature to prevent the burning or cremation of human bodies after death. The ground, as stated by the introducer of the bill, is that such bodies are generally imported from other States for cremation, and the practice is contrary to the instincts of humanity and to the Christian civilization of the age, and abhorrent to the masses of the people of the State. The penalty prescribed is a fine of from \$500 to \$1,000, or solitary imprisonment at hard labor for a period of from one to three years, or both. No action seems yet to have been taken further than the introduction of the bill.

THE TARIFF ON DRUGS.—The new tariff law, as passed by Congress at its recent session, fixes new duties on many drugs and chemicals. Some of the most important articles and the rates are as follows: Refined camphor, five cents a pound; croton-oil, fifty cents a pound; ammonia, twenty per cent. ad valorem; castor-oil, eighty cents a gallon; liquorice paste or roll, seven cents and a half a pound; liquorice juice, three cents; sulphuric ether, fifty cents a pound; nitrous ether, thirty cents; aqueous opium of opium, tincture of opium, and all other liquid preparations of opium, forty per cent. ad valorem; morphine, and all salts thereof, one dollar an ounce; all medicinal preparations, known as cerates, conserves, decoctions, emulsions, extracts (solid or fluid), infusions, juices, liniments, lozenges, mixtures, mucilages, ointments, pills, plasters, powders, syrups, etc., not specially rated, twenty-five per cent. ad valorem; proprietary preparations, such as cosmetics, pills, powders, troches, lozenges, syrups, cordials, bitters, anodynes, tonics, plasters, liniments, salves, ointments, pastes, drops, waters, essences, spirits, oils, or preparations or compositions recommended to the public as proprietary articles, or prepared according to some private formula, as remedies or specifics for any disease or diseases or affections whatever affecting the human or animal body, including all toilet preparations whatever used as applications to the hair, mouth, teeth, or skin, not specially enumerated otherwise, fifty per cent. ad valorem; all imitations of mineral waters, thirty per cent. ad valorem, etc. The free list embraces a larger number of articles than ever before, and among them are the following: Acquite, balm of Gilead, ipecac, cinchona or other barks used in the manufacture of quinine, crede camphor, unground ginger root, unground liquorice root, nux vomica, lavender, arsenic, sulphate and other salts of quinine, cinchonidine, vaccine virus, mineral waters not artificial, chamomile, muriate of potash, etc.

ECONOMICAL CREMATION.—The cost of cremating seven thousand bodies per annum at Bombay is said to be only £3,000, or rather less than ten shillings for each corpse.—*Med. Times and Gaz.*

DR. ALEXANDER J. STONE ON THE OLD CODE.—Dr. Alexander J. Stone, Vice-President of the American Medical Association and late President of the Minnesota State Medical Society, said in his presidential address:

"The code, since its final adoption, has apparently been laid upon the shelf by the side of the family Bible, to be treated with almost as much reverence, to be read quite as seldom, and to be quoted only when its provisions enable one to discipline a rival, or to exclude him from the benefits of professional affiliation. A judicial consideration of the code forces a conclusion that much which it contains is gratuitous insult to the profession, and more is rather calculated to amuse than to impress with respect the mind of the layman. There is not a

clause or sentence in the first two articles which is not absolutely true; but, should the self-evident truths contained in Article I be held constantly before the physician, as if by nature he was a brute who is to be taught the ordinary laws of humanity; a fool who must be taught a wisdom in the management of his patients which instinct alone would inculcate; a knave who must be withheld from empiricism; or a man without the instincts of a gentleman? Granted that men enter the ranks of the profession to whom the epithet of 'fool,' 'knave,' or 'clown' applies, of what value are the platitudes concerning brotherly love, or to what good is a formulated code defining the relations of medical men to the public or to each other? Among gentlemen such a code is unnecessary; among pirates it only serves to foster a cat-hauling hostility; as between a gentleman and a pirate, any difficulty which may arise is not to be satisfactorily settled by a reference to any code, because the standpoints from which each looks at matters differ too widely—nor are the penalties which the code imposes such as to deter a real rascal, nor is that unsovereign body, the medical profession, able to enforce its laws rigorously."—*Med. Age.*

THE "MEDICAL AGE" OF THE NEW YORK CODE.—In a recent issue the "Medical Age," of Detroit, says: "It is not our purpose to discuss the merits of the New York code at this time, or even to pronounce an opinion in regard to it. We desire merely to refer to the spirit in which it has been criticised by some of our contemporaries. That spirit has in many instances been a reflection on the toleration and fair-mindedness of the regular medical profession. From quarters, coming from which they have been a painful surprise, the criticisms have been of such a personal nature as to be entirely unworthy the organs of a liberal and high-minded profession. The motives of the framers and advocates of the code have been so coarsely impugned in them as to make it a compromise of proper professional dignity to even notice them, and the two journals in New York which have advocated the new departure have but increased the respect which their calm, dispassionate discussion of it has created, by not deigning to notice the ill-natured personalities which have been indulged in lieu of argument. Because when the matter was pending they, in an emphatic manner and in a legitimate spirit of controversy, discussed the defects of the old code and merits of the new; they were accused of being the tools of a coterie of New York specialists, and of advocating the change for sinister purposes. Now that, after the State society has taken final action, and when to continue the discussion would be 'stale, flat, and unprofitable,' as well as liable to irritate those of opposite views whose minds are thoroughly made up, they have let the matter drop, they are taunted with being not at all 'enthusiastic' or 'exultant' over the success which has attended their efforts, and are accused of having their ardor dampened by the disapproval of the profession, which from the beginning has placed only one estimate on the motives which have actuated this movement.' Exaltation over a defeated combatant is no longer regarded as either necessary or even pardonable among men of finer sensibilities. There was a time in the history of the race when such exaltation was quite in keeping, but we have outlived those days of animalism, and the qualities which are now regnant do not tolerate it, and not to exult is no longer regarded as by any means an evidence of practical defeat."

THE NEW CODE IN KINGS COUNTY.—At a meeting of the Medical Society of the County of Kings, held Tuesday evening, the 17th inst., the question of the attitude of the society on the code question came up. Dr. Kretschmar offered a resolution to the effect that the society accepted the action of the State society, and that the council be directed to bring the by-laws into conformity with that action. This was afterward withdrawn, and the subject was laid on the table. Finally, however, a motion was made by Dr. Prout, that the council be instructed to correspond with the State society, with a view to making the by-laws correspond with the requirements of the new code. This was carried by a large majority, without debate.

THE BOSTON WATER BOARD.—Among the appointments now before the Boston Board of Aldermen we find mention of that of Dr. John G. Blake as a Water Commissioner. The aldermen of Boston should certainly feel no hesitation to confirm so admirable an appointment.

SMALL-POX IN PENNSYLVANIA.—The "Tribune" has information to the effect that small-pox has been gaining ground rapidly of late in the region between Scranton and Carbondale, that the authorities of Dunmore have taken measures to prevent communication with the villages lying to the north of that place, that the schools in Oliphant, Dickson City, Throop, and Blakely have been closed, and that public vaccination has been ordered.

THE TRAFFIC IN DEAD BODIES.—According to the newspapers, this industry has been flourishing in Chicago for some time past, one Chaffee, the county undertaker, being reported to have sold three quarters of the dead bodies of paupers to the medical colleges, his revenue from this source exceeding \$6,000 annually.

THE NEW HAVEN MEDICAL ASSOCIATION.—A member was recently expelled from the association on account of his connection with a case of criminal abortion.

THE NEW YORK NEUROLOGICAL INFIRMARY.—An institution bearing this title and having for its object "the gratuitous treatment of the poor for all diseases of the nervous system" has been incorporated in this city. Dr. J. L. Corning, Dr. M. Josiah Roberts, and Messrs. Sidney Green, John T. Sherman, and Benjamin Crane have been elected trustees for the first year.

DEATH OF DR. FARR, THE STATISTICIAN.—William Farr, M. D., F. R. S., D. C. L., the well-known English statistician, is reported to have died on Monday, the 16th inst. For many years Dr. Farr devoted a great deal of patient and effective labor to the task of securing a systematic and intelligible registration of vital statistics, and to his efforts the methods now in general use are largely due.

OWING to the pressure upon our columns this week, we have been obliged to divide Dr. Flint's concluding article, and to postpone the publication of Dr. Piffard's second article, which will appear in our next number, as well as Dr. Flint's concluding remarks.

"THE MARYLAND MEDICAL JOURNAL."—The editors of this estimable journal announce that, beginning with the tenth volume, the first number of which will be issued May 3d, it will appear as a weekly, to be published every Thursday. Each number will contain sixteen double-columned pages. We congratulate the editors on this evidence of the continued prosperity of their journal.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from April 7, 1883, to April 14, 1883.*—ALEXANDER, CHARLES T., Major and Surgeon. To be relieved from duty at the United States Military Academy, West Point, New York, August 23, 1883. Par. 6, S. O. 82, A. G. O., April 1st, 1883. — BARTHOLF, JOHN H., Captain and Assistant Surgeon. The extension of leave of absence for twenty-three days by S. O. 37, C. S., Department of the Columbia, further extended one month. Par. 1, S. O. 31, Military Division of the Pacific, April 3, 1883. — GIBSON, R. J., Captain and Assistant Surgeon. Relieved from duty at cantonment on the Uncompahgre, Colorado, and assigned to duty at Fort Hays, Kansas. Par. 1, S. O. 73, Department of the Missouri, April 7, 1883.

NAVAL INTELLIGENCE.—The "Army and Navy Journal" mentions Surgeon J. H. Kidder as one of the officers of the steamer Albatross, which vessel has been fitted up with reference to scientific work, and will shortly leave for a summer cruise, after a magnetic survey at Norfolk. It is expected that she will go to London during the summer, as a part of our exhibit at the International Fish Exhibition.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, April 23d:* Medical Society of the County of New York. *Tuesday, April 24th:* Jersey City Pathological Society; Council of the New York Academy of Medicine; Dermatological Society (private); Surgical Society. *Wednesday, April 25th:* Medico-Legal Society; Pathological Society. *Thursday, April 26th:* Academy of Medicine (Section in Obstetrics). *Friday, April 27th:* Society of German Physicians (private); Clinical Society (private); Yorkville Medical Association (private). *Saturday, April 28th:* Medical and Surgical Society (private).

Lectures and Addresses.

ABSTRACT OF A LECTURE ON

HEALTH-FOODS, INVALID-FOODS, AND INFANT-FOODS.*

DELIVERED BEFORE THE NEW YORK ACADEMY OF SCIENCES,

BY PROFESSOR ALBERT R. LEEDS, Ph. D.,

OF THE STEVENS INSTITUTE OF TECHNOLOGY, HOBOKEN, N. J.

MR. PRESIDENT AND GENTLEMEN: Before proceeding to inquire into the relative value of health-foods, invalid-foods, and infant-foods, it is essential that we decide upon some criterion by which to judge of the value of foods in general; and for the present I have no better criterion to offer than that of considering food valuable according to the amount of mechanical energy it will supply, and here, as in all other cases, mechanical energy should be represented by heat. This heat is derived from some form of chemical combina-

tion, and the commonest source is from the combination of some of the constituents of a substance with oxygen. This combination we call combustion, or burning. Now, the same law that holds for combustion in general applies to the heat derived from the combustion of substances in the human body. Therefore, the law of Joule applies as well to the human body as to the action of a steam-engine. This law is simply that the amount of heat required to raise one pound of water from zero to one degree Fahrenheit is always represented by the amount of mechanical energy necessary to raise 772 pounds a distance of one foot. Or, in other words, if you let a 772-pound weight fall a distance of one foot, it will evolve enough heat to raise the temperature of one pound of water one degree Fahrenheit.

A distinguished English chemist, Dr. Frankland, was led by this method of reasoning to make some very careful experiments for the determination of the exact amount of mechanical energy represented by the heat that could be evolved by burning various articles of food. The way he did was to take the same amount of different foods and burn them, and then measure the amount of heat evolved from each; and this heat represented the mechanical energy stored up in each kind. The results of some of his calculations are shown in the table before you. In each case he took one pound of the food, and, after a careful combustion of it, he measured the amount of heat or mechanical energy evolved, not by the number of pounds, for then the figures would be too large, but by the number of tons that could be raised one foot high. He found, thus, that if he burnt a pound of pure albumin, he obtained an amount of mechanical energy equivalent to raising 2,643 tons one foot high. A pound of starch represented mechanical energy capable of raising 2,427 tons one foot high, a pound of wheat flour was equivalent to 2,383 foot-tons, a pound of lean beef to 885 foot-tons, of cane-sugar, 2,077 foot-tons, and a pound of beef fat gave the highest amount of all—namely 5,649 foot-tons. If, then, the combustion of these various kinds of food were as perfect in the body as Dr. Frankland obtained in his laboratory, we should obtain from them the enormous amount of energy represented by these foot-tons. But the fact is, that a certain amount of this energy is used up in the form of heat to keep the body warm and at its proper temperature, some in repairing the loss continually going on in the animal tissues, and part of it is represented in the waste matters that pass out of the system unused. So Helmholtz, on experimenting to find how much of the energy derived from food was available for use on the outside of the body in a healthy man, found that the mechanical work that could be done was represented by figures only one fifth the size of these large numbers representing the theoretical amount of energy in the food.

These calculations are sufficient for our present purpose, which is, merely to arrive at an approximate estimate of the amount of each kind of food that the human body requires. To make such an estimate is apparently a difficult matter, but just as, if you burn a pound of coal or wood, it gives off a certain amount of carbonic acid and water in the smoke, while it liberates a certain amount of mechanical energy,

* And milk-sugar.

and, if we confine and measure the amount of carbonic acid and water evolved, we can tell how much fuel has been used, so, if we measure the products of combustion in the human body, which are carbonic acid from the lungs, and water from the skin, and waste matter in the other excretions, we can reason back and find the approximate amount of mechanical energy which has been evolved by a given quantity of food. It has thus been found that the mechanical energy equivalent to the formation of all these products of combustion in the human body for one day is equal to a weight of 4,000 tons raised one foot high. This represents the total daily waste of a man in health weighing 154 pounds, and the actual quantity of these waste products in such a man is $8\frac{1}{2}$ pounds daily. Now, it is evident that, if we are burning up our tissues at that rate, in order to maintain our present weight the daily supplies of food must be equivalent to the amount of waste, and, therefore, the average amount of food for a man must be $8\frac{1}{2}$ pounds daily. But from this we may subtract $1\frac{1}{2}$ pound for the weight of the oxygen in the air we breathe, and this leaves 7 pounds to be accounted for; then we may subtract 5 pounds more as the weight of the water we drink, or that is contained in the food or taken into the system in other ways, and this, therefore, leaves only $1\frac{1}{2}$ pound as representing the entire amount of dry material a man should eat to supply the total daily waste of his system. This total daily waste is measured by certain amounts of each of the elements—carbon, hydrogen, oxygen, and nitrogen principally, besides small quantities of sulphur, phosphorus, and a variety of other mineral salts; and this being the case, it follows that these same elements must all enter in as a part of the $1\frac{1}{2}$ pound daily supply of food. These elements exist in the food as combinations of water in the proportion of 81 per cent.; fat, 3 per cent.; compounds of C, H, and O, 11 per cent.; of C, H, O, and N, 4 per cent.; and saline matters, 1 per cent.

You will see I have placed these theoretical computations of the composition of food at the top of my table, and immediately below I have placed the results of analyses as to the composition of human milk and of cow's milk; and then of wheat as representing the most nutritious of vegetable foods, and of beef the most nutritious of animal foods. These figures representing the composition of cow's milk are the mean of a large number of examinations of the milk of the cows in New Jersey, and represent very nearly the average composition of milk delivered in the city of New York. The analyses were made by the method of Ritthausen for both human and cow's milk.

An examination of these figures in the table shows that human and cow's milk approach far more nearly the theoretical composition of human food than any other article in the table. But it may be said that, in attempting to find out the best composition for human food, we should not be guided by mere theoretical notions, but we should find out by experiment the best composition for health foods. And this has, in fact, been determined by elaborate quantitative tests. If a food is all it should be, it ought to supply all the wants of the body, and no part except the non-nutritious portions be ejected. But there is practically no substance

known that will entirely fill that rôle. Cow's milk is not, if taken alone, a suitable continuous food for an adult, for the nitrogenous matters in it, or albuminoids, are not all assimilated, and, if taken alone, the assimilation is not so perfect as when it forms part of a mixed diet. It has been shown that when an infant two or three months old was fed on cow's milk alone, while the albuminoids could be perfectly assimilated, a considerable proportion of the fatty matters could not; and J. Forster says that on feeding a child of four months with cow's milk, and a decoction of rice and water in the proportion of one part of cow's milk to four of the decoction, he found that nearly one third of the fat of the cow's milk was not assimilated, and he obtained 34 per cent. of ash. As regards human milk, it is found that one twelfth of the fat is not assimilated by infants. Therefore, we may conclude that this fat either plays no part in the animal economy of the child, or else it subserves some purpose not yet understood.

Before attempting to decide whether or not human milk is the best food for an infant, I wish to ask your attention to one or two other points, and the first is the importance of taking notice of the ratio existing between the substances in a food containing nitrogen—that is, food composed of C, H, O, and N, or albuminoids—and those substances which do not contain nitrogen, but only carbon, hydrogen, and oxygen—that is, substances containing carbon with the elements of water, and known as carbohydrates. It is found that the substances containing nitrogen are those which are chiefly concerned in building up and repairing the waste of the body; that is, they supply nourishment to muscular, brain, and nerve tissues, and they may, therefore, be called the flesh-formers of the body, while the carbohydrates are simply burned up into carbon dioxide and water, and are useful to supply fuel to the system, and so may well be called the fuel-producers of the body. Neither of these classes is exclusively a flesh-producer or fuel-producer, however, but each can, to a certain extent, take the part of the other. Yet it is very important to recognize the general division of food substances into two great classes—albuminoids and carbohydrates. Now, as you look over this table of the composition of different foods, it might seem that, if we knew the percentage of albuminoids and carbohydrates in the composition of each, we could easily determine the relative values of the different foods simply by observing the ratio of these two great classes to each other. But, before relying upon such calculations, let me warn you that it will not do to simply add together the numbers representing the percentage of albuminoids in the composition of a food, and compare it with the number representing the percentage of fats and carbohydrates in order to determine its value, for this reason. Dr. Frankland found by his experiments that one pound of beef fat would give off in combustion an amount of mechanical energy represented by 5,600 foot-tons, while arrowroot starch gave off but little more than 2,000 foot-tons of energy; and, therefore, in a pound of beef fat there is nearly three times as much power, or heat, as in an equal weight of arrowroot starch. To multiply the power of the carbohydrates by three to determine the relative power of fats is, however, considerably too high

an estimate practically. For, in those well-known physiological experiments made at Munich by Pettenkofer, he showed that the true ratio between the amount of mechanical energy set free by the burning up of fat in the body to that of other foods made up of carbohydrates was as 1.75 to 1. Now, when we remember this fact, and turn to our table and begin by observing the composition of our theoretical food, we find that the ratio of the albuminoids to the carbohydrates is here as 1 to 4, and that ratio is higher than in any one of the other foods in this table except that of beef, where the proportion of albuminoids is twice as great as the carbohydrates. This ratio of the albuminoids to the carbohydrates in any food I speak of as the "ratio of nutrition." In the theoretical food it is 1 to 4; in woman's milk it is 1 to 7; and in cow's milk 1 to 3.2.

I speak with some diffidence on this matter, because I find in setting down these calculations that I am at variance with those set down in the elaborate work of König; but König based his calculations upon analyses of a vast number of samples of both cow's and human milk, which analyses were made by the older and less exact methods. He arrived at the conclusion that the ratio of nutrition in human milk was as 1 to 5.2, and in cow's milk as 1 to 3.4. Very greatly to my surprise, I found, on making some thirty analyses of samples of normal woman's milk, from patients under the care of Dr. A. M. Thomas, of the Emigrants' Hospital at Ward's Island, that the ratio of the albuminoids, according to my own analyses, was even lower than that stated by König. I found it but 1.7, or but one half that in cow's milk. In most of the text-books of medicine I find it stated that the ratio of the albuminoids to the carbohydrates in cow's milk is so much greater than in human milk that it is necessary in feeding infants to diminish in some way the relative amount of albuminoids. This statement is based upon the observed differences of composition as determined by analyses, and its correctness has been amply verified by both laboratory and experimental investigations.

The second important point to which I wish to call your attention is this: If you take human or cow's milk and coagulate it by rennet, you will find that the curd of human milk falls in very finely divided coagula, but that of cow's milk forms a sort of cheesy mass, broken up into large and hard clots. This difference in the coagula must largely depend upon the character of the albuminoids in the milk itself. And, in the ordinary analyses of milk, all these albuminoids are classed together and spoken of as consisting of albumin and casein. But, if a narrower scrutiny were made, a great difference would probably be found between the composition of the albuminoids in woman's and in cow's milk.

When it is found necessary to substitute cow's for human milk, the advice is given to dilute the cow's milk to the average strength of human milk; but it is evident, if this is done, that the ratio of the albuminoids to the carbohydrates will still be the same as before. The better plan, therefore, is to add to the watery portion of the milk something like the extract of barley or oatmeal, or the like, until a similar percentage of albuminoids is reached as in human milk. It

seems probable that there is something specific in the malt derived from barley or oats, which, when added to milk, alters the condition of the clot and makes it more like that of human milk, and so is more easily digested by infants. It seems to me, therefore, a question worthy of investigation, whether adding such substances as gum, gluten, dextrin, starch, and extracts of barley or oatmeal, may not be the best way of overcoming the objections to substituting cow's for human milk. And, in fact, this is just what has been done in the manufacture of these milk foods. In the farinaceous foods the diluent is principally starch, in the milk foods it is largely sugar and starch, and in Liebig's foods it is gum, or dextrin and sugar.

Now I have come to the most important matter of the lecture, and that is, the consideration of the proposition, at one time sincerely made, of substituting some other food for human milk as being a better food for infants. But the proposition to make this substitution is sustained neither by theoretical nor by experimental facts. Nevertheless, when it becomes a matter of necessity to substitute something else for human milk, then we will have to consider the claims of these various substitutes and compare together their real and not their advertised merits. Now, when we come to analyze these different manufactured foods, we find that they will all fall into one of three classes, and these are: (1) Farinaceous foods, (2) milk foods, and (3) Liebig's foods. I may also say here that each one of these is claimed by its manufacturer to be the best, if not the only fit food, to be used by infants.

Two years ago my colleague, Professor Thurston, from over-work was suffering from mental and physical prostration, which led to a deficiency of nutrition; so he determined to attempt to supply the want, and at the same time continue his severe mental work, by subsisting on foods composed principally of substances rich in albuminoids, or rather nitrogen, such as farinaceous preparations rich in gluten, with the result, he says, of increasing his vigor and prolonging his life. The foods that he was principally using at that time were those made by a company in New York that had been organized for this purpose, and known as the Health Food Company, and they were said to be rich in gluten. When he related these facts to me I told him that the foods he had been taking so long and with such advantage were said to contain no gluten, showing him a communication in a medical journal by Dr. E. Cutter, who stated that there was no gluten in these health foods. Dr. Cutter's pictures of microscopical examinations of them contained no gluten cells at all, and hence he stated that they were unfit for food, and worse than common flour. Thereupon my friend asked me to investigate this matter, and make an examination of these foods myself; and I did so, with the results I have set before you. But I was surprised to find that a physician of this city, Dr. Jacobi, was led to believe by these statements of Dr. Cutter that these manufacturers were perpetrating wholesale frauds upon the community. I have no question that Dr. Jacobi indorsed this article before making an extended personal investigation into the truth of its statements. Nevertheless, great wrong was done to the manufacturers of these foods, who, I think,

were honestly endeavoring to build up the health of the community. All of us, no doubt, feel at times that we need something to supply our exhausted nervous forces. These manufacturers were faithfully endeavoring to produce something to supply this need, and so I think that injury was done them by making too unqualified statements. Now, each of these manufacturers, as I said, advocates his own food as the best. There is no question that they are all trying to attain one end; but one tries in one way and another in another, and so each thinks that his method is the one best adapted for the purpose.

If we calculate the nutrition ratios of these various foods, we will find a great difference among them, and their values are to be measured by this nutrition ratio not only, but also by their relations to the processes of assimilation and digestion, and so on. Some of the earliest substances used by these manufacturers were farinaceous foods—such as tapioca, starch, and the like. But, after a time, physiologists found that the practice of giving starch to infants had serious objections, because in the system the starchy matters of food are not digested as such, but they are first converted into sugar, and so must be broken up primarily, and the power of effecting this conversion is much less in the infant than in an adult. This fact may be illustrated by a simple experiment. If you put a small bag full of starch into the mouth of an infant, the saliva acting upon it causes the decomposition and conversion of an extremely small portion of the starch into sugar, but the amount capable of being changed rapidly increases as the infant grows older. But Liebig devised a solution of this problem in this way: he said: If the infant lacks the material necessary to convert starch into sugar, we can make this conversion for him. He was familiar with the fact that in making ale or beer such a conversion is always effected. In this process, when the malt of the barley comes in contact with the wheat, the diastase of the barley causes the starch of the wheat to be broken up, and an infusion of dextrin and sugar is obtained. Liebig proposed to do this same thing for the child, because in it there is a deficiency of the ferment of the saliva, known as ptyalin, by which the starch of food is converted into sugar. So he proposed and made Liebig's food by taking malted barley and wheat and putting them in water and heating them together for half an hour, and then straining off the water and mixing the solution, after straining, with milk. This is Liebig's theory for infant foods. Liebig wanted the mothers in Germany to prepare their babies' food in this way; but, unfortunately, they were so thoughtless or careless that they would not take the trouble to do this, and so at last the work of preparing it fell into the hands of manufacturers. We, therefore, in these foods have the starch converted into dextrin and sugar, and a certain amount of albuminoids is left behind.

If now you will look at the table, you will see that Savory & Moore's food has about 36 per cent. of starch, and 20 per cent. of grape- and 99 per cent. of cane-sugar, besides nearly 10 per cent. of albuminoids. Mellin's food has no albuminoids, but it has a high percentage of glucose, while the remainder is principally dextrin and gum. In Horlick's food there is 6.71 per cent. of albuminoids, 12

per cent. of cane- and 35 per cent. of grape-sugar, and no starch, and it looks, therefore, as if the conversion of the starch here had been quite perfect. In the case of Hawley's food we find the albuminoids are 5 per cent. and the unconverted starches 11 per cent., and there is 3 per cent. of cane- and 41 per cent. of grape-sugar. Keasbey and Mattison's foods have no albuminoids and no starch, but a high percentage of grape-sugar and a moderate percentage of cane-sugar, and this preparation not only looks like but smells like molasses. Baby sup is the worst of all, for very little of the starch has been converted into sugar. This is not exactly the kind of food that Liebig intended for feeding infants, I think.

After Liebig's time came up the proposition to take a farinaceous body and combine the various elements of a perfect food by adding milk to it, thus making a combination of farinaceous substances and cow's milk. These are known as condensed milk and milk foods, and they are the only artificial foods containing any considerable amount of fats. The American-Swiss is one of the best of the milk foods, and it contains 6.8 per cent. of fats. One shortcoming is in the amount of sugar in these milk foods, and it would seem as though it would be a great forward step in their preparation if we could avoid this difficulty by mixing farinaceous matters and milk without adding so much sugar.

There is a step forward being now made which I think will prove a triumph. The introduction of condensed milk was a great boon, but recently the advance has been made of making a milk food that will keep without any sugar scarcely. This is called preserved milk. I have got two samples of preserved Alpine milk containing only 4.13 per cent. of cane-sugar, and if you dilute this with water to the same consistency as natural milk, you will get almost the same composition as in cow's milk. This is an advance that marks an era in these matters, and I think it will prove ultimately to be a great public boon.

When the analysis of these different foods showed me that they fell into these three classes, I went to a number of distinguished physicians, who had tried them in their practice, to get their opinion as to the relative value of each class, and I fully expected that they would tell me that they found different results in feeding infants and children on different varieties of food; but I was immensely disappointed in the results of my investigations, not only among the physicians of New York, but also of Philadelphia and Boston, and I was astonished to find that in almost every case their verdicts were the result of personal experience only. When I find such results from the use of foods so very different in character, it almost draws me to the conclusion that the principles on which the manufacture of these foods is based are not the real ones which determine the utility of a food. If a physician can prescribe Mellin's food, which contains no starch, and get the same results as with imperial granum, which has 79 per cent. of starch, or Ridge's food, with 78 per cent. of starch, then it would seem that the idea of Liebig, that unchanged starch was an improper thing for a child's food, is not founded on fact. And is it, therefore, not necessary to come back to another idea, and that is, the question whether

the real utility of cow's milk does not depend on the principle suggested some time ago, that its digestibility is increased by adding something to it to coagulate it into a different kind of clot? That is to say, does not the real utility of it as a food depend upon whether we introduce something like gum, or starch, so as to throw down a finely divided coagulum, or by omitting to do this do we not permit the formation of a hard insoluble coagulum?

Before concluding my lecture, I will take a few moments and throw upon the wall a few magnified pictures, as illustrations of these various food substances. These are photographs of a microscopical image of the substances, and the first is a sample of ordinary milk; 2d, wheat starch granules; 3d, barley starch granules; 4th, imperial granum; 5th, grains of wheat; 6th, starch cells and wheat cells; 7th, wheat starch, and the same after moist baking, and after boiling the granules; 8th, starch granules baked dry; 9th, section of a barley grain; 10th, barley starch granules after they have been liberated from their envelopes.

One word more in conclusion. A few days ago, in reading a lecture by Dr. Meigs, of Philadelphia, I found he spoke of the fact that, out of every 100 children put under the care of the physician in the almshouse of Philadelphia, 100 children died. The fact is monstrous!

I shall feel repaid for all my efforts in this important matter if anything I may have said here this evening shall have induced any one of you to think more on this subject, and to agree with me that if there is any subject where, least of all, the cupidity of manufacturers ought to step in, it is the subject of infant foods.

Original Communications.

MEDICAL ETHICS AND ETIQUETTE.

COMMENTARIES ON THE NATIONAL CODE OF ETHICS.

By AUSTIN FLINT, M. D.

CONCLUDING REMARKS.

The proposal to write commentaries on our National Code of Ethics may have conveyed to the minds of many an idea of presumption. The writer of the foregoing commentaries indulges the hope that their perusal has not sustained this idea, inasmuch as he has not ventured to take issue with the code on any important point except one—namely, the ground for refusing medical consultations. Nor has he assumed to be an expounder of the code, but only to supplement comments in conformity with the spirit which pervades it. In fact, a leading motive has been to excite the attention of medical, and, perhaps, also, to some extent, non-medical readers, to the code itself. There are many members of the medical profession who have never read the code with that degree of interest which it claims, and there are some who have never read it. These assertions are based on information obtained by personal inquiries. It is safe to say of the public that not one in a thousand knows anything of its character and provisions. If the

publication of the code in connection with the commentaries may lead in any measure to the diffusion of a better knowledge of it, the writer would have the gratification of feeling that he had done a good work. When it is considered that this ethical code was adopted by the American Medical Association thirty-six years ago without a dissenting voice, that it has remained without any alteration by the association up to the present time, and that it has been accepted without any modification by every medical organization which has adopted any code throughout our country, how can any one doubt that it must be remarkably free from objectionable features! Were it otherwise, such an extraordinary unanimity of approval for so long a period would have been impossible. But the code in itself affords the best evidence of its intrinsic excellence. It is a collection of ethical principles and rules which can not but commend themselves to the approbation of every one. Their excellence has never been questioned. No one can doubt that complete conformity to them would secure for the medical profession, in the highest degree, purity, humanity, and universal respect.

The writer is not one of those who apparently have a fondness for disparaging the medical profession of this country. He believes that a large proportion of the members of the profession are desirous of conforming to the Code of Ethics. He believes, moreover, that, from the standpoint of the observance of medical ethics, the profession of America will compare favorably with that of any other country. If this view be correct, much is to be attributed to the influence of our national code, and it is a rational conclusion that this influence will be increased by a more general knowledge of its teachings and requirements. For this end, knowledge of the code should be made a part of medical education. Schools of medicine should not assume that, as a matter of course, graduates will make themselves acquainted with it. It should be brought to the attention of medical students, and its precepts inculcated by their teachers. Conformity to it should be embraced in the obligations formally acknowledged when the doctorate is conferred. Recent events, which are now to be referred to, will, it is hoped, be ultimately productive of good by directing greater attention to the code, and enhancing its importance in the minds of the profession.

The New York State Medical Society, at its annual meeting in February, 1882, adopted, as a substitute for the National Code of Ethics, the following:

CODE OF MEDICAL ETHICS.

- I. THE RELATIONS OF PHYSICIANS TO THE PUBLIC.
- II. RULES GOVERNING CONSULTATIONS.
- III. THE RELATIONS OF PHYSICIANS TO EACH OTHER.

1.—*The Relations of Physicians to the Public.*

It is derogatory to the dignity and interests of the profession for physicians to resort to public advertisements, private cards, or handbills, inviting the attention of individuals affected with particular diseases, publicly offering advice and medicine to the poor without charge, or promising radical cures; or to publish cases or operations in the daily prints, or to suffer such publications to be made; or, through the medium of reporters or interviewers or otherwise, permit their opinions on medical and sur-

gical questions to appear in the newspapers; to invite laymen to be present at operations; to boast of cures and remedies; to adduce certificates of skill and success, or to perform other similar acts.

It is equally derogatory to professional character, and opposed to the interests of the profession, for a physician to hold a patent for any surgical instrument or medicine, or to prescribe a secret nostrum, whether the invention or discovery or exclusive property of himself or others.

It is also reprehensible for physicians to give certificates attesting the efficacy of patented medical or surgical appliances, or of patented, copyrighted, or secret medicines, or of proprietary drugs, medicines, wines, mineral waters, health resorts, etc.

II.—*Rules governing Consultations.*

Members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity.

To promote the interests of the medical profession and of the sick, the following rules should be observed in conducting consultations:

The examination of the patient by the consulting physician should be made in the presence of the attending physician, and during such examination no discussion should take place, nor any remarks as to diagnosis or treatment be made. When the examination is completed, the physicians should retire to a room by themselves, and, after a statement by the attending physician of the history of the case and of his views of its diagnosis and treatment, each of the consulting physicians, beginning with the youngest, should deliver his opinion. If they arrive at an agreement, it will be the duty of the attending physician to announce the result to the patient, or to some responsible member of the family, and to carry out the plan of treatment agreed upon.

If in the consultation there is found to be an essential difference of opinion as to diagnosis or treatment, the case should be presented to the patient, or some responsible member of the family, as plainly as possible, to make such choice, or pursue such course as may be thought best.

In case of acute, dangerous, or obscure illness, the consulting physician should continue his visits at such intervals as may be deemed necessary by the patient or his friends, by him, or by the attending physician.

The utmost punctuality should be observed in the visits of physicians when they are to hold consultations, but, as professional engagements may interfere or delay one of the parties, the physician who first arrives should wait for his associate a reasonable period, after which the consultation should be considered as postponed to a new appointment. If it be the attending physician who is present, he will, of course, see the patient and prescribe; but, if it be the consulting physician, he should retire, except in an emergency, or when he has been called from a considerable distance, in which latter case he may examine the patient, and give his opinion in writing, and under seal, to be delivered to his associate.

III.—*The Relations of Physicians to Each Other.*

All practitioners of medicine, their wives, and their children while under paternal care, are entitled to the gratuitous services of any one or more of the faculty residing near them, whose assistance may be desired.

Gratuitous attendance can not, however, be expected from physicians called from a distance, nor need it be deemed obliga-

tory when opposed by both the circumstances and the preferences of the patient.

The affairs of life, the pursuit of health, and the various accidents and contingencies to which a medical man is peculiarly exposed may require him temporarily to withdraw from his duties to his patients, and to request some of his professional brethren to officiate for him. Compliance with this request is an act of courtesy, which should always be performed with the utmost consideration for the interests and character of the family physician, and, when exercised for a short period, all the pecuniary obligations for such service should be awarded to him. But if a member of the profession neglect his business in quest of pleasure and amusement, he can not be considered as entitled to the advantages of the frequent and long-continued exercise of this fraternal courtesy without awarding to the physician who officiates the fees arising from the discharge of his professional duties.

In obstetrical and important surgical cases, which give rise to unusual fatigue, anxiety, and responsibility, it is just that the fees accruing therefrom should be awarded to the physician who officiates.

Diversity of opinion and opposition of interest may, in the medical as in other professions, occasion controversy, and even contention. Whenever such cases unfortunately occur, and can not be immediately terminated, they should be referred to the arbitration of a sufficient number of physicians before appealing to a medical society, or the law, for settlement.

If medical controversies are brought before the public in newspapers or pamphlets by contending medical writers, and give rise to or contain assertions or insinuations injurious to the personal character or professional qualifications of the parties, the effect is to lower in the estimation of the public not only the parties directly involved, but also the medical profession as a whole. Such publications should, therefore, be brought to the notice of the county societies having jurisdiction, and discipline inflicted, as the case may seem to require.

In justice to the medical profession of the State of New York, the number of votes by which the foregoing "new code," as it is called, was substituted for the national code, should be stated and kept in mind. The substitution was carried by 52 yeas against 18 nays. A two-thirds majority of seventy persons thus decided to substitute a code in which a large part of the national code is abrogated, and to insert in the portions retained a modification which, as will presently be seen, is of great importance, thereby severing fellowship, by means of representation, of the State society and of county societies with the American Medical Association, as well as with societies in other States.* Those of the medical profession of the State of New York who

* The following is the ninth by-law of the American Medical Association: "No State or local medical society, or other organized institution, shall be entitled to representation in this association that has not adopted the Code of Ethics, or that has intentionally violated or disregarded any article or clause of the same." In accordance with this by-law, the Judicial Council of the association, at the annual meeting in 1882, decided as follows: "Having carefully examined the Code of Ethics adopted by the New York State Medical Society at its annual meeting in February, 1882 (or furnished by the secretary of said society), the Judicial Council find in said code provisions essentially different from and in conflict with the Code of Ethics of this association; and, therefore, in accordance with the provisions of the ninth by-law of the American Medical Association, they unanimously decide that the said New York State Medical Society is not entitled to representation by delegates in this association."

had no expectation of such changes in the national code, and who were taken by surprise at the action of the State society, seemed to think that, as a matter of course, the action would be reversed at the next annual meeting. But, to complete the history, at the meeting in February, 1883, a motion for a reversal was lost, 99 voting for and 105 against it. Thus, at the present time, the New York State Society and the affiliated county societies in the State are ostensibly committed to the adoption of the new code. The New York Academy of Medicine, which has no connection with the State society except that it is empowered to send delegates to that body, retains the national code in its by-laws, and the fellows of the academy are therefore bound to it as fully as hitherto. It is not proposed to engage here in a controversial discussion of the reasons assigned for the action of the State society respecting the ethical code, and still less to inquire into personal motives. Some remarks, however, offered in a spirit of courtesy, may not be out of place.

Why more than one half of the national code was left out of the new code has not, so far as the writer knows, been explained. The omitted portion embraces the "duties of physicians to their patients," the "obligations of patients to their physicians," the "duties for the support of professional character," and the "obligations of the public to physicians." Certainly the duties and obligations as specified in the omitted portions of the code can not be objected to. It can do no harm to specify them. They do not occupy so large a space in print that it was advisable to eliminate them in order to curtail the length of the code. The only conceivable explanation of their omission is that they were considered as superfluous. But it may be that they who voted for their elimination judged incorrectly, however naturally, from their own consciousness. A personal sense of rectitude is not always a safe guide in judging of the importance of ethical rules for self-government in others. There are many persons who are not liable to the temptation to steal or commit murder, but no one will probably contend that, for this reason, the commandments relating to these offenses should be dropped from the decalogue.

The important modification in the portion of the national code which is retained in the new code is in this sentence: "Members of the medical society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine." Since the discussions to which the substitution of a new code has given rise relate almost exclusively to this sentence, it is fair to conclude that herein is the gist of the matter. The point is that a legal qualification renders consultations permissible. Narrowing further the object of the modification, the practitioners of homœopathy have hitherto been excluded from consultations by an interpretation of the Code of Ethics; they are legally qualified practitioners, and, at the present time, they constitute the great majority of those with whom consultations have been considered as interdicted by the code. The question, therefore, now at issue in the State of New York is simply this: Shall consultations with homœopathic practitioners be permitted? The affirmative answer to this question is based

chiefly on two reasons—namely, first, the requirements of humanity; and, second, the legal status of homœopathic practitioners. These reasons are specious but invalid. It is a gratuitous reflection on the National Code of Ethics to imply that it interdicts professional services under any circumstances in which they are required by humanity. It was quite unnecessary to introduce into the new code the following sentence: "Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity." To intimate that this rule of action is in violation of the national code is a monstrous injustice to it and to the medical profession. As regards the legal status of homœopathic practitioners, this has nothing to do with the question at issue. It would be strange indeed if a State Legislature should undertake to regulate the professional ethics of physicians. This has never been attempted, and it probably never will be. The argument that a legal status affects in any measure the status as regarded from the standpoint of medical ethics seems to the writer too trivial to call for refutation. It will be time enough to consider seriously this argument when fellowship with all classes of practitioners is made compulsory by statute, and this is equivalent to an indefinite postponement.

The true ground for declining professional fellowship with any class of practitioners has been considered in the commentaries on that portion of the national code which relates to consultations. This ground is not a professed belief in the vagaries of Hahnemann, or in any other dogmas. It is the adoption of the names homœopathic, eclectic, botanic, etc., as a trade-mark; the formation of a sectarian school of practice, announced to the public as such, and the endeavor, in divers ways, to bring the regular medical profession into popular disrepute. The physicians who became the early disciples of Hahnemann were not driven out of the ranks of the profession; they made haste to go out of their own accord, and to announce to the public their secession. Then, as now, it suited their ends not to be regarded as simply practitioners of medicine. Then, and ever since, they have sought for popular patronage as a sect detached from the regular profession. Their success in obtaining practice is due to the belief entertained by their patrons that they have had sagacity and independence enough to break away from antiquated doctrines and traditional rules of therapeutics, supplanting these by the great discoveries of the founder of the sect. Under these circumstances, can members of the medical profession, imbued with a proper sense of professional honor, do any act which involves affiliation with homœopathic practitioners? The clause in the new code which sanctions consultations with them is a concession of honor, and a concession which has been publicly treated by them with scorn. Moreover, the concession implies a confession of error in the past; for, if the recent action of the State Medical Society be right, the medical profession has been in the wrong for the past thirty-six years!

The action which substituted a new code for our time-honored National Code of Ethics has brought upon the profession of the State of New York a great disaster. It

has substituted for harmony, dissension, with all the evils flowing therefrom—evils affecting not only the profession, but communities. Has this result been sufficiently considered? Granting honesty of purpose to those who originated and who have carried on with persistent efforts the movement against the national code, is it not the part of wisdom to pause and reflect upon these evils? Should not a measure fraught with such consequences command, to say the least, a large majority in its favor? Would it not be becoming in the ardent advocates of the measure to recognize the propriety of some approach to unanimity of opinion, and for this end be content to await the result of a fuller discussion and a longer period of deliberation? Finally, if the national code need revision, it is desirable that whatever changes are made should be uniform throughout the country, not differing in the different States of the Union. Therefore, in closing these remarks, the writer earnestly appeals to those who advocate the new code, and to those who are in favor of no code, to join hands with those who uphold the national code in submitting all questions concerning professional ethics to the American Medical Association, and to abide by the decisions of that body.

THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.

By HENRY G. PIFFARD, M. D.

Second Article.

In our last we presented the medico-political or legal relations of the profession. In this we will consider the medico-educational.

The oldest of the existing medical colleges is the College of Physicians and Surgeons. This institution was chartered, not directly by the State, but by the regents of the university, in the year 1807. It was at that time virtually the same corporation as the New York County Society, or, in other words, the county society was constituted a medical faculty, with authority to teach and grant diplomas. This intimate relationship was not long maintained. The teaching body obtained independent powers, and was subservient, to a slight degree only, to the county society as such. The relationship, however, was not wholly dissolved, for, a few years later, when the college exhibited an unbecoming laxity in the granting of degrees, the society exercised its powers and influence to break up these practices. Since that time there has been, so far as we are aware, no special scandal connected with the management of its affairs. As an alumnus of the institution, we feel pride in stating that it has, before all others, been careful in the exercise of its corporate powers. This statement, however, is not true of some other colleges that were in existence during the early part of this century. The granting of diplomas was so lax that the State declared they should no longer be a license to practice ["The degree of doctor of medicine conferred by any college in this State shall not be a license to practice physic or surgery," Act of 1827, Sec. 21]. Subsequent to this time several new colleges were organized, which, in their charters, obtained the

right to make their diplomas licenses to practice. At the present time the diploma of every legally incorporated medical college in the State carries with it the license to practice. On the other hand, no medical college in this country or elsewhere issues a diploma which entitles its bearer to practice in this State, except with the approbation of one of the college faculties of this State. It matters not whether the candidate has drawn his inspiration from Gross or Buchanan, he must first satisfy a college faculty of this State of his fitness to practice before he can become a legally qualified practitioner in this State. As before noted, the entire responsibility concerning the qualifications of practitioners coming into the State from without the State rests with the colleges. For the assumption of this responsibility they are entitled to exact a fee of twenty dollars in each case.

Until recently there were thirteen colleges capable of exercising these powers. Of these, eight professed to teach non-sectarian medicine, located, four in New York city, one in Albany, one in Syracuse, one in Buffalo, and one in Brooklyn. Two taught homeopathy, both located in New York; two were of the eclectic persuasion, both in New York; and one, the "College of Physicians and Surgeons" of Buffalo, was a nondescript. These colleges all possess the power of granting the degree of doctor of medicine, and their diploma carries with it the license to practice in the State, after the graduate shall have complied with the registration law of 1880. The legal requirements for graduation are the same in all—namely, three years' pupillage with a legally qualified practitioner (not necessarily of this State), attendance on two full courses of lectures, the last of which in the college granting the degree, and the passage of a satisfactory examination in the seven principal branches of medical science. It is safe to say that the requirements in the matter of examination have not been identical in the thirteen institutions. As regards the regular colleges, there have been no public scandals connected with improper graduation of candidates, at least of late years. The same can be said of the homeopathic colleges, but can not be said of either of the eclectic colleges. The "Eclectic Medical College" of New York has been very strongly suspected of issuing diplomas contrary to law. Suspicion was first directed toward the other eclectic institution, known as "The United States Medical College," in consequence of the receipt by the officers of the New York County Society of a communication from the Illinois authorities asking the status of said college. The communication further stated that a person armed with the diploma of that institution had applied for a license to practice in Illinois, under circumstances that led them to suspect that he had obtained his diploma illegally. This led the officers of the society to watch the college, and, on examination, they became satisfied that the college itself was not legally incorporated, and they instituted a suit against it. The Supreme Court of the State has, within the past few weeks, rendered a decision to the effect that the college was *not* legally incorporated, and hence that none of its diplomas are legal. In Erie County the same may be said. The College of Physicians and Surgeons of Buffalo stood on exactly the same footing as the

United States College, and a similar suit against them has resulted in a similar decision from the Supreme Court. We have now but eleven medical colleges, against thirteen of a year ago. How much further the shrinking process will extend it is impossible to foresee. "The mills of God grind slowly, yet they grind exceeding small," and the profession of this county may rest assured that, if they give their officers proper moral and financial support, illegal practice and quackery of all sorts will be an exceedingly hazardous pursuit.

It may, we think, be truthfully stated that, at the present time, quackery* and unqualified practice prevail here to a less extent than in any other State in the Union, with the exception of the States of Illinois and North Carolina. On the other hand, the States in which it flourishes most luxuriantly are Massachusetts and Pennsylvania, the latter State claiming to be the banner State of the old code, while the former has a special code of its own that is, in some respects, even more stringent than that of the American Medical Association. If we turn now to the States of Illinois and North Carolina we find that in the former quackery flourished to an alarming extent just so long as the profession was actively aggressive toward sectarian medicine. As soon, however, as it joined hands with sectarianism for the purpose of putting down quackery, it then began to triumph over the common enemy. This joining of hands occurred when the Illinois State Board of Health was established, in which were representatives of the regular, the homeopathic, and the eclectic schools. In North Carolina the case was somewhat different. In that State the profession had never allowed the subject of sectarianism to trouble them very much. If a homeopath by any chance settled among them, they very sensibly let him alone. They neither persecuted nor prosecuted him. They gave him no opportunity to play the martyr, or to parade his grievances in public. We have been curious to learn the outcome of this policy, and, on inquiry, have been informed that, of fourteen hundred physicians in that State, there are but six homeopaths, and, so far as known, no eclectics. In contrast to this let us cite the neighboring county of Kings in our own State. Many years ago a gentleman of homeopathic proclivities applied for admission into the county society. He was refused membership. He carried the matter to the courts, and obtained a decision in his favor. He did not join the Kings County Society, however, as in the mean time a homeopathic society had been formed of which he became a member. By the continuance of the same policy the Kings County regulars succeeded in building up against themselves a pretty strong sectarian organization, and now rejoice in one homeopath to about every six regulars, a larger proportion of homeopaths than will be found, we believe, in any other portion of the United States. New York city has about one homeopath to ten regulars.

This digression aside, we return to the subject immediately under consideration, namely, the medico-educational status of this State. Of the eleven medical colleges, three

may be placed in the front rank as regards importance and facilities for medical instruction. Ranking with them are two colleges in Pennsylvania and one in Massachusetts. These six colleges compete for and obtain the patronage of the better class of students, the one in Massachusetts, however, possessing a higher standard for entrance than the others. One of the colleges of this State emulated the example of Harvard, and declared that it would require an examination of the student's fitness before permitting him to matriculate. This declaration was regarded by the profession at large as an indication that the faculty of the college were determined to elevate the standard of medical education in the State, and in this way contribute to the elevation and maintain the dignity and honor of the profession. We all know how the experiment terminated. After one year's trial the faculty reconsidered its resolution to require a preliminary examination, and resumed its former status. The two other colleges, however, have made some substantial advances; one of them, by enlarging its building, adding laboratories, etc., has increased its facilities for teaching, and the other has materially lengthened its lecture course. At the present time the clinical advantages, the facilities for instruction, and the quality of instruction actually given in this city, are, we believe, unsurpassed by any to be found elsewhere in this country. The other colleges in the State have, according to their opportunities, done well, and, in some respects, have shown a more progressive spirit than the metropolitan institutions.

This, then, is the medico-educational status at present. What it will be in the future it is impossible to foresee. There are evidences, however, that thoughtful minds in the profession are looking and hoping for still greater improvement. This may take the shape of a single board of examiners, or the establishment of a medical college so largely endowed that the number of the students and of graduates will not be a material factor in the requirements of the college, or possibly the State or the municipality may itself assume the prerogative, as in several European countries, of educating those who aspire to be physicians. These, however, are questions that do not appear to exact immediate settlement, nor is such settlement at present possible.

In our next we will consider the medico-ethical status of the profession in this State.

REMARKS ON THE GENERAL ARCHITECTURE OF THE NERVOUS SYSTEM OF MAN.

By AMBROSE L. RANNEY, M. D.

ADJUNCT PROFESSOR OF ANATOMY IN THE MEDICAL DEPARTMENT OF THE UNIVERSITY OF THE CITY OF NEW YORK.

THE second set of fibers to which I would now direct attention are of equal importance from a physiological point of view. Originating from the midst of a plexus of cells in the cortex, they accompany the commissural fibers to the point where the former diverge to the opposite hemisphere, after which a separation takes place. These fibers do not pass to the opposite hemisphere, but concentrate

* By quackery we here mean the practice of medicine by uneducated and legally unqualified persons; while by sectarian medicine, practice in accordance with some special method or doctrine.

themselves, in the region of the superior angle of the ventricle, into bundles placed in close juxtaposition, and are inserted, as a late author expresses it, like "pins in a pin-

in which they are found. They are supposed to be so distributed to the different portions of the cortex of each hemisphere as to act as commissural fibers for the different zones. Whether they are always distinct fibers, or simply thread-like anastomoses of the processes arising from the cells of the cortex, is not as yet fully determined. By some authors these fibers are described as dipping downward for some distance into the white substance of the hemispheres and then returning to the cortex, while others describe them as bundles of fibers of varying lengths which invest the inner surface of the cortex.

Broadbent claims to have established the existence of a set of fibers which pass from posterior portions of the cerebral cortex to the white matter of the spinal cord without traversing the substance of the basal ganglia, but the statement is not as yet fully accepted by the majority of observers.

The cerebral cortex serves as a receptacle for the various impressions of the external world, as portrayed to it by means of the nerves of sensation and the special senses. It has been considered, therefore, by Meynert as analogous to a *projection plane*, the outer world being the projected object; and the nervous system has been subdivided by the same author into three distinct members of a "*projection system*," comprising nerve-fibers and various ganglia interposed along the course of the centripetal and centrifugal tracts. The views of this author may be stated as follows:

The first member of the projection system consists of the fibers which are connected with the cortex and which terminate chiefly in the interrupting gray matter of the basal ganglia. The second member of the system comprises the fibers of the crus cerebri, which spring from the basal ganglia and end in the tubular gray substance. Most of these fibers are supposed to cross the median line to reach the opposite side of the spinal cord. The third member of the system embraces the nerves which arise from the tubular gray matter, from the point of origin of the third cranial nerves to the termination of the spinal cord.

It will be perceived that the first member of the system properly embraces the fibers of the cerebral lobes—the commissural, radiating, and associating systems of fibers. It is probable, moreover, that the gray matter of the cerebellum (chiefly that of the cerebellar cortex) is intimately connected with the cortex of the cerebrum by still another set of fibers, which constitute a distinct formation, but the ramifications of which can not be so described in this general introduction as to be easily comprehended in all of their anatomical relations.

It may be asked, "Why is there a necessity for the breaking of the nerve-fibers and the introduction of cell elements in the course of a tract which might be continuous?" "What is the object of so disturbing the simplest form of arrangement?" "What is the function of the nerve-cells so interposed?"

It is not possible, with our present knowledge, to answer all of these inquiries to our complete satisfaction. We have, however, sufficient data for the conclusion, at least, that these interruptions in the course of nerve-fibers are not solely for the purpose of effecting a simple interchange

FIG. 4.—DIAGRAM OF THE COMMISSURAL FIBERS ON THE LEVEL OF THE CORPUS STRIATUM. (Luy.)

1, 1', groups of transverse fibers, one within another, continuous with those in the previous figure; 2, 2', gray substance of corpus striatum; 3', groups of inferior commissural fibers; 4, 4', these curve into the shape of an S to accommodate the corpus striatum, which they help to limit externally.

cushion," into the basal ganglia of the hemisphere from whose periphery they take their origin. These are commonly called "*radiating fibers*," from an analogy between the direction which they take and the rays of light reflected from the surface of a hollow sphere. By some authors they are designated as "*converging fibers*," because they tend to become focused about the basal ganglia. By others the term "*peduncular fibers*" is employed, because they are destined to pass into the crus cerebri. By directing our attention for a moment to the fact that fibers which arise from or are distributed to all portions of the cortex are forced to make their passage from and into the spinal cord through the foramen magnum, in case they are to be distributed to parts below the head, we shall understand why they are properly converging fibers before they become collected into the circumscribed limits necessary for their transmission through this foramen of the cranium. It is important to bear in mind that *this set of fibers has nothing in common with the opposite hemisphere*. The physiological function of the radiating fibers of the cerebrum consists simply in the transmission of impulses of a centripetal and centrifugal variety from and to the cortex cerebri. It is by means of these nerves that *sensory impressions* received from without are recorded upon the sensory portions of the cortex, and *motor impulses* transmitted from the motor regions of the cortex to the muscles of the trunk and extremities. As Meynert aptly puts it, "the sensory nerve-fibers constitute the feelers of the cortical cells, the motor nerves, the tentacles, as it were."

A third set of fibers exist within the white substance of the cerebral lobes, called "*associating fibers*" ("*fibræ arcuatae*"—"collateral fibers"). These, as was the case with the preceding set, are confined exclusively to the hemisphere

of excitations between different groups of ganglion-cells, placed one above the other, as buckets are passed up and

form the corpus striatum); one also connected with the optic thalamus and the adjacent corpus quadrigeminum; and, finally, a bundle of fibers whose course differs from that of the others—those of the fornix. The latter appear to connect certain regions of the cortex with the anterior tubercle of the optic thalamus. It is claimed by some authors that some of the radiating fibres (those of the internal capsule of the cerebrum) are continued directly from the cortex to the crus without the intervention of ganglion-cells. The diagram now introduced will aid in following these details.

In the second member of the projection system—the crus cerebri—marked alterations may be observed, in regard to the number, course, and arrangement of the nerve-fibers, from those of the cerebrum. The actual number of fibers seems to be markedly reduced by passage through the substance of the basal ganglia. The fibers are, moreover, gathered into two bundles in the crus, whereas in the cerebrum they form several bundles before the interruption of these ganglia. The two bundles of the crus have been named by Meynert the "*basis cruris*" (the "*crusta*") and the "*tegmentum cruris*," from their relative position to each other. The fibers of the former are connected chiefly with the nuclei of the corpus striatum (as can be seen in the diagram), which constitute its crown, as it were; those of the latter with the optic thalamus and the corpus quadrigeminum. Physiologically, the basis cruris or crusta may be regarded as a centrifugal or motor

FIG. 5.—DIAGRAMMATIC REPRESENTATION OF THE FIBERS IN THE CEREBRUM. (Lc Bon.)

down a ladder from hand to hand (using an illustration borrowed on account of its aptness). There is a morphological significance, not to be overlooked, in these interruptions, which can often be demonstrated. These interposed cells possess the power of deflecting the current passing along the nerves to which they are attached, as the switch is used in telegraphy and on railroads. By the use of this simple device, the centripetal and centrifugal currents may be allowed to pass without interruption when necessity demands it; or, again, the direction of the current may be changed and transmitted, through some other connection which the cell possesses by means of fibers attached to some other of its processes, to a point not situated upon the direct line of the paths of the projection system. We have reason, also, to believe that each of these nodal masses of gray matter has an automatism of its own, by which it can influence the nerve-fibers in intimate association with it without the intervention of the larger ganglia above, which are capable of controlling it when necessary.

GENERAL ARRANGEMENT OF THE FIBERS OF THE PROJECTION SYSTEM.

The systems of fibers found in the cerebral lobes have already been discussed at some length, but certain additional facts pertaining to the radiating system remain untold. Sections of the cerebrum are of aid in mapping out various bundles into which the radiating fibers are grouped. We are enabled to determine with ease groups connected with the caudate nucleus and the lenticular nucleus of each hemisphere (the two masses of gray matter which together

FIG. 6.—DIAGRAM OF THE COURSE OF SENSORY AND MOTOR TRACTS IN THE MESOCEPHALON AND HEMISPHERES. (SQUID)

S, sensory tract in posterior region of mesocephalon, extending to O and T, occipital and temporal lobes of hemispheres; M, motor tract in basis cruris, extending to P and F, parietal and frontal lobes of hemispheres; C, Q, corpus quadrigeminum; O, T, optic thalamus; N, L, nucleus lenticularis; N, C, nucleus caudatus; 1, the fibers forming the "*tegmentum cruris*" (Meynert); 2, the fibers forming the "*basis cruris*" (Meynert).

tract, and the tegmentum cruris as a centripetal or sensory tract. In studying the brains of mammals, these two bun-

dles and the ganglia connected with them give evidence of an independence of one another which governs the development of each. Where the frontal and parietal lobes are large, we find the basis cruris and the nuclei of the corpus striatum highly developed; on the other hand, when these lobes are at their minimum we find the tegmentum cruris and its ganglia developed in excess. There is also physiological evidence to sustain the opinion that the basal ganglia and the two bundles of the crus are capable in themselves of executing, in response to excitation from without, all varieties of movements in an animal deprived of its cerebral lobes (above the level of the basal ganglia) with a nicety and exactness which are astonishing.

The crus suffers a diminution in the fibers of its motor bundle (basis cruris) after its entrance into the substance of the pons Varolii. This is very apparent when the large size of the tract, before its entrance into the pons, is contrasted with the small anterior pyramid of the medulla oblongata, which is its direct continuation after its exit. The explanation of this fact is as follows: All of the radiating

tem, and is endowed with some power either of control of or subtle influence over motor impulses.

If we examine a sagittal section of the pons Varolii and crura, we shall perceive that the pons performs for the cerebellum an office analogous to that which the corpus callosum performs for the cerebral hemispheres—the transmission of commissural fibers which connect homologous portions of the two lobes. We may perceive, furthermore, that these commissural fibers of the pons subdivide the fibers of the basis cruris and tegmentum cruris into smaller bundles or fasciculi. In addition, nodal masses of gray matter may be detected in both the crus and pons. It is reasonable, therefore, to conclude that the cells of these nodal masses of gray substance establish some form of communication between the fibers of the projection tracts and the commissural fibers of the cerebellum, independent of the fibers of the basis cruris which deflect themselves from the path of the projection system into its substance. The cerebellum, furthermore, has undoubted association with special fibers of the cerebrum (which are prolonged, subsequently, into the basis and tegmentum cruris) by means of two of its prolongations, viz., the *processus e cerebello ad testes* and the valve of Vieussens. The multiplicity of connections which this ganglion has with fibers of the projection system leaves its probable functions a matter of speculation. The theories advanced will merit consideration later in the course.

The ganglia of the brain have intimate relation with certain nerve-tracts which are independent of the projection system proper—viz., the fibers of special cranial nerves, which are more or less independent of the tubular gray matter. The olfactory, optic, and auditory apparatuses must be considered, therefore, as modified types of projection systems, which bear, however, striking analogies to the projection system extending to nerves of spinal origin, although possessing peculiarities of structure essentially their own. In these modifications of the general arrangement, the middle projection fibers seem to be wanting, as there is no organ which corresponds exactly with the central gray tube. Many observers, however, incline to the view that the peripheral ganglion-cells are analogous to the tubular gray matter; these consider, for example, the fibers of the optic tract as a *middle* system of projection, and the radiating fibers in the retina as the external system of projection.

The projection tracts of the crus are prolonged into the spinal cord, where they become more or less intimately associated with the tubular gray matter. The third member of the projection system exhibits an augmentation in the actual number of fibers over those found in the crus, as there can be no doubt that the total number of fibers in the spinal nerves exceed greatly those comprised in the basis and tegmentum cruris. Here, again, we have undisputable evidence that the gray matter of the cord, by means of its cell elements, serves as a means of conduction of nerve impulses, and also as a point of origin for additional nerves, whenever demanded. The fibers of the basis cruris become joined to cells in the gray matter of the spinal cord, which are connected with the *anterior* or *motor roots* of the spinal nerves (see Fig. 2). Those of the tegmentum cruris unite with similar cells which lie more posteriorly, and are asso-

FIG. 7.—A DIAGRAM OF THE BRAIN IN TRANSVERSE VERTICAL SECTION. (Dalton.)

- 1, crus cerebri; 2, internal capsule; 3, optic thalamus; 4, corpus striatum; C. C., corpus callosum; L. N., lenticular nucleus; S, fissure of Sylvius; F0, gyrus fornicatus; F', first frontal convolution; F'', second frontal convolution; F''', third frontal convolution; T', first temporal convolution; T'', second temporal convolution; T''', third temporal convolution; H, gyrus hippocampi.

fibers of the cerebrum, which become intermingled with the gray matter of the corpus striatum (the caudate and lenticular nuclei), and which escape from that ganglion as fibers of the basis cruris, are not destined to form parts of the projection system. The ganglion-cells of the basal ganglia exercise, in the case of some special cerebral fibers, the switch-like action previously referred to, and deflect the impulses, which they carry, to the cerebellum; hence, in the pons, quite a large bundle of distinct fibers leave the direct tract of the basis cruris and pass to the cerebellum (through the *processus e cerebello ad pontem*), and thus establish a communication between the cerebral cortex and that ganglion. This fact, in addition to others which will be brought forward later, leads to the conclusion that the cerebellum is, in some imperfectly understood way, brought into direct relation with the motor tract of the projection sys-

ciated with the *posterior* or *sensory roots* of the spinal nerves (see Fig. 2). The individual course of the various bundles, which help to form the motor and sensory tracts of the crus, through the medulla and spinal cord, will be described in a subsequent paper. It may be well, however, to state in general terms that each separate fiber which properly belongs to the projection tract of the crus finds its course interrupted by the interpolation of a ganglion-cell before it reaches the particular spinal nerves with the action of which it is to become intimately associated. These nerve-cells of the spinal cord explain the various phenomena which are comprised under the head of spinal automatism; since, in the beheaded animal, no other source of reflex motor action can be discovered, although its existence has been demonstrated beyond a doubt, both in animals (Pflüger) and even in man (Robin). By the interpolation of nerve-cells in the course of nerve-fibers, sensory impressions may be carried to any one of the three main divisions of gray matter, and there excite a response in the form of a motor impulse, viz., the tubular gray substance and its expansions, the basal ganglia, or the cortex of the cerebrum.

Book Notices.

A Manual of Histology. Edited and prepared by THOMAS E. SATTERTHWAITE, M. D., Professor of Histological and Pathological Anatomy in the New York Post-Graduate Medical College, etc., in association with Drs. Thomas Dwight, J. Collins Warren, William F. Whitney, Clarence J. Blake, and C. H. Williams, of Boston; Dr. J. Henry C. Simes, of Philadelphia; Dr. Benjamin F. Westbrook, of Brooklyn; and Drs. Edmund C. Wendt, Abraham Mayer, R. W. Amidon, A. R. Robinson, W. R. Birdsall, D. Bryson Delavan, C. L. Dana, and W. H. Porter, of New York. Second edition, enlarged and revised, containing two hundred and two illustrations, with an appendix. New York: William Wood & Co., 1882. Pp. xvi-490.

As the first edition of this work has already been noticed at length, it is unnecessary to examine each chapter separately. The additions which have been made to the text are not important, and will be found principally in the appendix. The present volume is most attractive in appearance, with its neat binding, clear type, and complete index. That the book has been received favorably is proved by the speedy issue of a new edition. Whatever doubts some readers may have as to its intrinsic value as a text-book "of wider scope" than the less pretentious manuals of histology, it would be most ungracious to criticise too severely the accomplished gentlemen who have given their time to its preparation. But, as a real *guide* to the student in his microscopical studies, we leave it to the judgment of the reader whether it will supplant those which are already in the field.

Without being hypercritical, we would ask whether the wood-cuts are not too diagrammatic to suit the inexperienced observer.

Not to disparage the original investigations, notably that of Dr. Warren on the fat-columns, we still insist that the book does not give the student an idea of how other men have worked to obtain the results stated, and how he shall follow in their footsteps.

With all deference to the editor, we believe that the plan which he so ably inaugurated in the first part of the book has not been carried out in the succeeding chapters. Having prepared us for a manual, we find (as he acknowledges in the preface to the first edition) that this is really a text-book. In our opinion, the bibliography at the end of each chapter is the most valuable feature of the volume, and will for this reason render it of considerable interest to the advanced student. In conclusion, we have only to add that, in spite of the unevenness which generally characterizes the work of so many different hands, there is evidence of a careful sifting process throughout. Unnecessary details are mainly avoided, and there is a constant effort to omit all that is unpractical and unproved. The best proof of the success of a book is its adaptability to the class of readers for whom it was written. Time alone will prove if we are not correct in the inference that Dr. Satterthwaite's manual will be used more for hasty reference than as a practical guide.

L'Année médicale (quatrième année) 1881. Résumé des progrès réalisés dans les sciences médicales. Publié sous la direction du Dr. BOURNEVILLE, Médecin de l'Hospice de Bicêtre, etc. Paris: E. Plon et Cie., 1882. Pp. vi-444.

This is a brief *résumé* of the most important advances made in medicine during the year 1881. More comprehensive in its scope than Braithwaite's "Retrospect," "L'Année médicale" will prove a valuable work of reference for those who have not the time for an extended search through journals devoted to special subjects. The chapters on anatomy and physiology are rather brief, the former being devoted principally to recent researches in the nervous system. General medicine and surgery are treated of at length, renal disease in particular receiving considerable attention. There is an interesting section on the localization of cerebral lesions, with special reference to the phenomenon of aphasia. Peritoneal surgery receives several pages. Ophthalmology and otology are treated of at length. Under urinary surgery reference is made to recent nephrectomies, to the Bigelow-Thompson controversy on rapid lithotripsy, and to the advisability of laparotomy in cases of rupture of the bladder. The chapter on obstetrics is largely devoted to the phenomena of pregnancy. Under operative obstetrics, the reader will note with surprise that the barbarous operation of symphysectomy has been performed fifty times by Morisani, of Naples, forty mothers and forty-one children being saved! The chapter on gynaecology is to a great extent anatomical, and is the least satisfactory in the book. Under therapeutics, prominence is given to the use of hypodermic injections of water, which are said to be efficacious in ovarian dysmenorrhœa. Resorcin is mentioned as a valuable germicide. The volume ends with brief biographical sketches of the prominent medical men of the world who died during the year.

BOOKS AND PAMPHLETS RECEIVED.

Dr. G. Beck's *therapeutischer Almanach*. 10 Jahrgang, 1883. Des Taschenbuches der neuesten Therapie III. Bändchen, 1. Heft. Bern: J. Dulp, 1883. 32mo, pp. 76.

Quarterly Report of Medical Officers, United States Army, with their Stations and Duties, as reported to the Surgeon-General April 1, 1883.

Fortieth Annual Report of the Managers of the State Lunatic Asylum at Utica, for the year 1882.

Seventh Biennial Report of the Board of State Commissioners of Public Charities of the State of Illinois.

Alcoholic Inebriety from a Medical Standpoint, with cases from Clinical Records. By Joseph Parrish, M. D. Philadelphia: P. Blakiston, Son & Co., 1883. Pp. 185. [Price, \$1.25.]

THE
NEW YORK MEDICAL JOURNAL,

A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, APRIL 28, 1883.

THE ACADEMY OF MEDICINE AND THE ETHICAL CON-
TROVERSY.

At the last regular meeting of the Academy of Medicine, held Thursday evening of last week, the President, Dr. For-dyce Barker, being in the chair, Dr. Austin Flint, Jr., moved the following resolutions:

Whereas, The New York Academy of Medicine adopted in its by-laws, as its standard of medical ethics, the Code of Ethics of the American Medical Association; and

Whereas, Each newly elected member of the Academy is required to sign its constitution and by-laws; be it

Resolved, That the Committee on Admissions is hereby instructed to report to the Academy for election as resident Fellows no physician who is known to the committee to be in opposition to the code of the Academy, and who, as a consequence, can not consistently sign the by-laws of the Academy.

Resolved, That these instructions to the Committee on Admissions be continued in force until the American Medical Association shall have modified or repealed its code of ethics, and such modification and repeal shall have been adopted by the Academy, or until the Academy shall have modified or repealed its by-laws referring to medical ethics.

The resolutions having been seconded, Dr. C. R. Agnew moved that they be laid on the table, in order that time might be given for those opposed to their passage to be notified and to have an opportunity of being present at some subsequent meeting, when they could be taken up and acted upon. It was very evident, he remarked, from the presence of a large number of supporters of the old code, that, although no notice had been given on the card of announcement that any such topic would be brought up, measures had been taken to pack the meeting.

Dr. D. B. St. John Roosa followed, with remarks in the same strain, adding that the temper of the meeting was not spontaneous, but that it had been created by a secret society that ordered its members to be present on certain occasions. Dr. Roosa was frequently interrupted by jeers and derisive laughter, which the President found it difficult to quell. After some further talk, of rather a stormy character, the resolutions were carried by a vote of fifty-eight to twenty-five, the ayes and nays being called. Dr. Flint moved a reconsideration of the vote, and Dr. J. W. S. Gouley moved that the question be postponed indefinitely. "Is it Dr. Flint's object to throttle the Academy?" asked Dr. Agnew. "Undoubtedly," replied Dr. Flint. The effect of the vote to reconsider and to postpone indefinitely is, of course, to prevent a subsequent reversal of the action taken.

The following resolution, also introduced by Dr. Flint, was then passed:

Resolved, That the Academy hereby disavows any sympathy with the action of the State Medical Society, which has put the profession of the State, through its State and county societies, in an attitude of opposition to the medical profession of the rest of the United States.

The President, Dr. Barker, the Vice-President, Dr. R. F. Weir, the Treasurer, Dr. W. F. Cushman, Dr. Roosa, and Dr. Agnew tendered their resignations, whereupon Dr. S. S. Purple said: "I hope the gentlemen have paid their dues." This was greeted with a storm of hisses. Without acting upon the resignations, the Academy then adjourned, to meet on the first Thursday in October.

The readers of this journal will remember that Dr. Austin Flint, Sr., in a letter addressed to Dr. Barker (see our issue of March 24th, p. 332), asked the following questions: "1. Is it not unwise to consider the question as settled by a small plurality of votes? 2. In a matter of such great importance, involving as it does the liability to a division of the profession into two parties, does not a sound policy dictate that there should be at least some approach to unanimity of sentiment? 3. Is it not best that those who entertain opposing views should be content to await longer deliberation and a fuller expression of opinions throughout the State, with the expectation that there will be a nearer approach to unanimity than is now apparent?" It will also be remembered that, in his reply to this letter, Dr. Barker deprecated the heated discussion of ethical questions, i. e., the only sort of discussion of such matters that it seems possible to secure at society meetings. Following the publication of this correspondence between Dr. Flint and Dr. Barker, it seemed for a time that the course they joined in advising had commended itself to the minds of those who had before been active in the sort of discussion alluded to. We can not but regard it as unfortunate, therefore, and calculated to drag the ethical discussion down again into the mire of vituperation, that the subject was brought up before the Academy of Medicine. When, on a former occasion, it was sought to bring it up in a meeting of that organization, the elder Dr. Flint saved the Academy from dissension by pointing out that such discussions could more properly be pursued in the county society—a suggestion that was hailed with acclamation by the great majority of those present, without regard to diversity of sentiment on the merits of the question. Dr. Flint's service to the profession on that occasion will not soon be forgotten. If anything could add to the esteem and reverence with which we all regard him, his action at that time would have furnished ample motive.

The Academy of Medicine is essentially a scientific body. It ought to be neutral ground in regard to the controversy which now threatens to divide the profession into two hostile camps. We see no good reason why a dignified discussion in written articles, prepared in the calmness and sense of responsibility that come to men when they sit down to address their fellows in that formal way, but which vanish at the first acrimonious word spoken in an assembly, can not yet be looked upon by both parties in this struggle as not only amply sufficient, but altogether the most likely to conduce to the speedy, orderly, satisfactory, and permanent solution of what some months ago

we characterized as the problem with which the profession in this State was called upon to deal. It has been with that feeling that we have yielded up much of our space for several weeks past to papers bearing upon the questions at issue. This we have done, although it involved postponement of the publication of a good deal of matter of a scientific nature. It is because we have been impressed with the necessity that the issues involved in the problem should be scrutinized by our readers in the light that was to be shed on them by men of diverse views, because we deprecated the snap judgment that alone has scope in extemporaneous debate, that we have followed this course. We still believe that our readers will bear with us if we continue in the same course, and we still trust that dignified and temperate discussion in print will not be thrown aside in favor of methods which, let them be adopted by whichever side they may, are far removed from what the deliberations of an enlightened and beneficent profession should be. Our columns are still open, to any reasonable extent, to calm and dispassionate statements and arguments bearing upon ethics, and we hope that the argument in favor of the old code will not be allowed to rest wholly on Dr. Flint's shoulders. Admirably as he has presented the subject, we feel that there must be others who could contribute to the full statement that seems now in every way desirable.

It is pitiable to reflect that, at the late meeting of the Academy, men who for years have labored side by side in the study of our art, each proud of the other's achievements, were so arrayed against each other that, to borrow a phrase from one of the newspapers, they seemed anxious to bring their scalpels into play in another cause than that of scientific work. We make no comment on the methods that were said to have been followed by the party that carried the resolutions. If the thing were to be done, it was but human nature to resort to such devices, although in the end such a victory, so achieved, is always apt to lead its promoters in the path of disaster. Neither do we attach any particular importance to the action taken; the resolutions simply reaffirmed a part of the organic law of the Academy. Whatever import may justly be accorded to that evening's work arises simply and wholly from the fact that it gave rise to an angry discussion at a time when moderation, charity, and a decent construction of men's views and actions are most to be wished for. It is most fortunate that, in the confusion in which the meeting became involved, the resignations that were tendered were not acted upon. Between now and October, we trust, peace and harmony will reign again within the walls that have heretofore rung to the voices of Barker, the two Flints, Agnew, Roosa, Weir, Gouley, and hosts of other tried and cherished men—in a cause how different from this unseemly wrangle!

THE MICHIGAN MEDICAL BILL.

A BILL has been introduced into the Senate of the State of Michigan, providing, as we understand, that all persons now practicing medicine as permanent inhabitants of the State shall be considered as legally qualified, that itinerant practitioners

shall pay a monthly fee of one hundred dollars, and that in each senatorial district a board of three medical examiners shall be appointed by the senator, subject to confirmation by the Governor, who, acting under and in conjunction with a central board of three appointed by the Governor, shall be charged with the duty of examining persons desirous of practicing medicine in the State (exclusive, we presume, of graduates of its own medical colleges), either as to their actual attainments or as to their legitimate possession of a diploma from an institution authorized to confer the degree of doctor in medicine.

Commenting on this bill, the "Detroit Lancet" says: "The medical profession of Michigan is far better off than the profession in any State having a law regulating the practice of medicine." And it then goes on to deprecate legislation of this sort. Now, such a law as we have outlined is by no means to be regarded as in a very high degree satisfactory, but, on the other hand, it seems to us calculated to accomplish some good, and to do no particular harm, provided, of course, the Governor and the several senators take reasonable pains to look out for the public interest in making their appointments of examiners. But the point to which we would call attention is, that medical legislation, either in Michigan or anywhere else, is not necessarily intended to be in the interest of the medical profession as a corporate body. Nor is it desirable that it should be. Ours is not a paternal Government, and God forbid that it should ever become one. The common impression is, however, that all medical legislation is set on foot either as a measure for promoting the material welfare of the profession as a whole or as a means whereby one or another of the so-called "schools" of medicine may obtain an advantage over its rivals. This impression seems to have taken a firm hold upon the legislative mind, and every legislator is prone to say to himself, whenever a medical bill comes up, "*timeo Danaos et dona ferentes*." Being thus led to look askance upon anything in the shape of proposed legislation bearing upon the status of medical practitioners, it is scarcely to be wondered at that the people's representatives in the various State Legislatures feel an instinctive impulse against favoring the passage of such measures. We can not suppose that our contemporary is ignorant of this tendency on the part of law-makers, and therefore we can only regret that its words (by mere inadvertence, we feel bound to take for granted) make in favor of the error to which we have alluded. As a matter of fact, it can not be too forcibly impressed upon the public mind, and especially upon the legislative mind, that, whenever the medical profession supports legal enactments affecting its status, it does so wholly in the interest of the community, and not for any sordid purposes of its own. Beyond its good repute, medicine has little if anything to gain by the repression of quackery—certainly no commercial advantage; and our brethren who have the ears of legislators should take pains to set us right in the matter.

THE CONNECTICUT STATE BOARD OF HEALTH.

At various times we have commended the work done by the boards of health of several of the States, notably that of

Illinois and that of West Virginia, both of which seem to have accomplished a good deal in the way of ridding their respective constituencies of the curse of charlatanism. The Fifth Annual Report of the Connecticut State Board of Health, for the year ending November 30, 1882, bears testimony that in that State also good sanitary work is being done. A handsome volume it is, of nearly five hundred pages, including the Registration Report for 1881, and we are quite sure that the expense incurred in its preparation will be made good to the people of Connecticut, with ample interest, in the way of lives prolonged and time saved that would otherwise have been lost from sickness, to say nothing of the improvement that should take place in the physical qualities of the population—results that can not but come as the direct consequence of such a general diffusion of a knowledge of sanitary science as publications of this sort are admirably fitted to secure.

The main labor of preparing this excellent report seems to have fallen upon Dr. C. W. Chamberlain, of Hartford, the secretary of the board, who, besides the general arrangement of the whole volume, has contributed interesting essays on "Milk as a Medium for the Transmission of Disease," on "Some of the Organic Impurities found in Drinking-Water," and on "Impure Ice." There are several other papers that ought to excite attention, notably Professor Lindsley's article on "The Uncertainties and Risks attending the Use of Proprietary and other Ready-made Medicines," with the sentiment of which, we may remark, we do not wholly agree, Dr. Page's paper, entitled "How can we escape Insanity?" Dr. Wilson's essay on "Epidemic Intermittent Fever: its Annual Progress in Connecticut and other parts of New England," a subject of the utmost practical moment, Dr. Lewis's "Microscopical Examination of Potable Waters in the State of Connecticut," and Dr. Cressy's admirable presentment of the subject of "Protective Inoculation."

MANUFACTURING PHARMACISTS.

IN the paper from which, in the foregoing article, we have expressed our dissent, Dr. Lindsley says: "The field over which the State Board of Health has cognizance is not limited to the study of the *causes* of disease, but includes also, to some extent, the means of curing diseases and of restoring health." He then enters upon a diatribe against "ready-made medicines." "Manufacturing chemists have appeared," he says, "and are growing in numbers with alarming rapidity. Not content with supplying the non-perishable official preparation for which there is possibly a legitimate demand, they have presumptuously encroached upon the domain of the therapist, and boldly propose new compounds, and recommend them to physicians with instructions as to the mode of use and the maladies to which they are adapted. Then with all the art of skillful advertising they *make*, literally *make*, a market for their pretended discoveries in the art of curing disease."

Now, although "these pe prave 'ords," the indictment does not strike us as very terrible. Nevertheless, it does seem to us uncalled for as an official utterance. We fully concede that the

Board of Health of the State of Connecticut, or any other sanitary organization, has not only a right to exercise, but a duty to perform, in protecting its community against fraudulent or inert pharmaceutical preparations; but we submit that this right does not make it proper to inveigh officially in general terms against an industry that is not necessarily, or, we believe, actually, detrimental to any public or private interest.

As a matter of fact, our manufacturing pharmacists have accomplished much for which the profession in general is quite ready to acknowledge its indebtedness; they have helped materially to carry the fame of American excellence in pharmacy abroad, as may be seen from the repute in which their preparations are held in Great Britain and in various other foreign countries. And, with all this, we have yet to see any evidence of their having worked an injury to the apothecary. Even taking the recent strictures of one of our contemporaries upon the quinine pills provided by some makers as founded on data strictly accurate—and it should be borne in mind that the accuracy of those data is questioned—who can suppose that the extemporaneous dispenser, who is called upon to make up a lot of pills according to a magisterial prescription, working hurriedly amid the customer's manifestations of impatience, will turn out work that can be more depended upon for uniformity than that which is produced on a large scale by skilled manipulators?

The American people have always resented pulpit interference with their temporal affairs; let the profession of medicine, in like manner, decline to sanction all official scolding in their name, especially when the occasion is so slender as in this instance, however many there may be who look back with regret upon the days of bulky and nauseous compounds.

THE "INDEX MEDICUS."

WE trust that few, if any, of our readers need to be told that the "Index Medicus" is a monthly journal devoted solely to bibliography. We regret to learn, however, that the profession need to be reminded that they have not yet given the "Index" that amount of practical support that is required to meet the expense involved in its publication. Being, so far as we know, the only medical journal of its kind in the world, and being in every way creditable to its editors and publishers, it certainly seems as if it ought to be a necessity to all who occupy themselves with medical writing or with research in current medical literature. We therefore trust that before long its support will be so increased as to put its continued publication beyond doubt.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

(Concluded from page 442.)

In the discussion* that followed the reading of my paper, Professor Henry H. Smith stated that he was not aware that any doubt existed among surgeons of the present day as to the advisability of ligating veins, although he was of the opinion that a diseased vein—e. g., varicose—would be apt to give trouble

* See "Philadelphia Medical Times," 1882, p. 664.

under conditions in which a healthy vein would do well, citing a case in which varicose veins of the legs were tied, and death ensued in five days.

Professor SAMUEL D. GROSS said that he had long been in the habit of ligating veins, and early in his professional life was impressed with the fact that the fear of such ligations was unfounded. He was opposed to lateral ligation, and thought it always best to tie the vein in its continuity. Varicose veins he would not ligate, nor would he excise an exposed vein, unless it could not be avoided. Professor S. W. GROSS stated that he was now cognizant of sixty cases in which the internal jugular vein had been tied; forty-seven of these were examples of ordinary deligation, of which one terminated in death by thrombosis; thirteen were instances of the application of a lateral ligature, of which four proved fatal from secondary hæmorrhage. The freedom from hæmorrhage after the ordinary procedure and the occurrence of fatal bleeding in more than one third of all cases after the lateral ligature were sufficient grounds for its exclusion from practice. He believed that veins may be ligated with as much confidence as arteries.

Dr. PACKARD stated that, in his experience, whether in cases under his own care or in the hands of other surgeons, ligation of veins had been attended by no bad results. Dr. Hunter stated that Dr. Agnew had ligated the internal jugular vein at its point of emergence from the skull, the ligature coming away at the end of the second week without unfavorable symptoms. Dr. Blackwood had seen during the war many cases of gunshot wounds of the vessels of the neck; whenever lateral ligation had been used, in the cases in whose after history he had been able to follow, a fatal result from secondary hæmorrhage had ensued. He had no fear in ligating veins, though he agreed that diseased veins do not bear ligation like healthy ones.

Dr. NANOREDE reported a case in which he had been compelled to keep the internal jugular vein exposed for a long time in an operation which was followed by prolonged suppuration, during which the vein was kept bathed in pus, without injury to it. He never hesitated to tie veins in the course of operations.

Dr. ALLIS had applied a lateral ligature to a wounded internal jugular vein, and had obtained rapid and permanent recovery. Dr. Parkes, of Chicago, had seen lateral ligation used in three cases of wounds of the internal jugular vein, with recovery in each case; while in one case, after complete ligation, death was occasioned in thirty-six hours from thrombosis.

Dr. KEEN could not agree with previous speakers as to the inadvisability of operating upon diseased veins. In varicose conditions he had several times exposed and ligated the veins at points one inch or more apart, and excised the intervening portion by the antiseptic method, and with excellent results. In his opinion the ligation of varicose veins by the catgut ligature was the best treatment.

It will be seen that the points upon which discussion was elicited involved the subjects of the safety of ligation in general, the propriety of the application of a lateral ligature in certain cases, and the effects of exposure and denudation of veins. Despite the freedom from disaster which had characterized the large experience of the eminent surgeons who took part in this discussion, and which, thus far, has likewise been enjoyed by myself, I am not quite prepared to dismiss as without foundation the opinions of the many other eminent observers who declare that surgical interference with veins does involve peculiar dangers. While so strongly expressed an opinion as that of Chassaignac, that "ligation is one of the most dangerous operations of surgery" ("Traité clin. et prat. des opérat. chirurg." t. i.), may not appear to be justified, or even that of Erichsen, that the application of a ligature to a vein "should, if possible,

always be avoided" ("Science and Art of Surgery," 1878, vol. i, p. 278), it is still undeniable that there are special hazards that attend the surgery of the veins. "The fatal catalogue of tied veins," referred to by Travers, the yearly deaths from inflammatory complications following phlebotomy, admitted by Trousseau, and the fatal cases of thrombosis reported by Ollier, remain each as types of a distinct class, to which fresh examples are from time to time being added of dangers that are peculiar to veins, and which ought, even in this day, to receive due attention from surgeons. The direction of the blood current in the veins toward the heart, through continually widening channels, and the favorable arrangement of the connective-tissue sheaths of the veins for the propagation along the course of the veins, as in lines of least resistance, of spreading suppurative inflammation, constitute the conditions which by their combination favor the production of disastrous complications after wounds of these vessels. The more accurate knowledge which recent research has given us of the etiology and pathology of these complications has made more emphatic the truth that, in addition to the predisposing causes, both local and constitutional, that may exist, the introduction of a continuously active irritant from without through a wound is essential to the establishment and extension of the morbid processes. Here we venture upon a field which is becoming yearly less and less debatable—that is, the agency of micro-organisms in the production of spreading inflammation. The differences in the intensity of the results of these agents in different cases seem to be due to differences in the resisting power of the tissues to which they gain access. The presence of defective resisting power gives a ready and sufficient explanation why, in persons depressed and enfeebled from any cause, a wounded vein should be more likely to give trouble than in the robust and vigorous. Also, it explains why the nutritive defects in the tissues that lie about varicose veins should be sufficient to render operations upon such veins extra hazardous. An important consideration in this connection, also, is that, in most instances, the resisting power of the tissues, though diminished, would still be sufficient to resist attack and accomplish repair without serious complication, if they were not submitted to extensive and repeated traumatism. Thus, from the point of view of the relation of micro-organisms to wound disturbances, the conclusion forces itself upon the conviction of the observant surgeon that in all cases care should be taken that a minimum of traumatism should be inflicted upon veins and their ensheathing connective tissue. Particularly when adequate measures to prevent the access of noxious micro-organisms are impracticable does the importance of fostering the natural resisting power of the tissues demand recognition. If the tissue conditions which attend varicose veins be taken as an example of a vulnerable tissue, it is easy to understand why so frequently disastrous consequences have followed operations upon them conducted without antiseptic precautions, and why, with such precautions, such disasters rarely, if ever, occur. In such procedures as the strangling of a varicose vein between an unirritating metallic pin inserted behind it and a compress laid over it upon the surface of the skin, or the subcutaneous injection into the neighborhood of the vein of a substance capable of exciting a local adhesive inflammation in the tissues reached by it, the two opposite conditions of wound treatment are exemplified: In the one, no protection from hurtful atmospheric constituents, but a minimum of local tissue irritation; in the other, a maximum of local tissue traumatism with exclusion of atmospheric germs. It is to be expected that excellent results should attend either method, though both are imperfect in their conception, and both more hazardous than methods in which the two conditions are combined—that is, methods by which both exclusion of noxious micro-organisms

is secured and a minimum of local tissue traumatism is produced.

The question of the relations of micro-organisms to the effects likely to follow involves, in addition to these differences in local tissue vulnerability exemplified in the case of varicose as compared with sound veins, the different constitutional susceptibility possessed by different individuals to the effects of micro-organisms, as Ogston ("British Medical Journal," March 12, 1881), when injecting micrococci pus into the tissue of mice, found that though the same dose was injected into each of a number of mice of the same litter, the effects greatly varied—one, perhaps the largest and strongest, escaping unscathed, or with but slight illness. In others, abscess developing; in some, necrosis; and in one, perhaps the smallest or most weakly, death from septicæmia. So also with the same amount of traumatism and the same exposure to the access of micro-organisms in operations involving veins, the most diverse effects may result in different individuals, though in all, whatever perturbation in the normal process of repair may have been present, the cause has been the same—poisoning by micro-organisms.

I will take the liberty of citing, as well illustrating the most grave consequences of poisoning by micro-organisms following operations upon veins, the case of operation for cure of an arterio-venous aneurysm which was reported to this society, April 26, 1881, by Dr. E. L. Keyes ("Va. Med. Month.," Dec., 1881). The patient was described as having been anæmic, and possessed of a low degree of vitality. The operation, at Bellevue Hospital, was difficult and prolonged; at its close there was a ligature upon the peroneal, upon the posterior tibial, upon the popliteal, and upon one other vein, while the aperture of the anterior tibial vein was occluded by a sponge saturated with a solution of subsulphate of iron. The patient rallied slowly from the ether, the wound did not granulate, but assumed first a dry pink, then a moist gray appearance, with some colored serum shortly before death. Forty-two hours after the operation there was a slight chill, followed by a condition of torpor, physical depression without delirium, terminating in death sixteen hours later. Just before death the temperature was found to be 105.25° F.

What was the source of the poison that so speedily overwhelped this patient and prevented even local reparative effort? No microscopical examinations of the tissue of the wound site in this case are recorded, but observations of similar cases by other observers (Ogston, *loc. cit.*, and, also, "Journal of Anatomy and Physiology," vol. xvii, p. 49), and experiments upon animals, have demonstrated that in such cases the wound tissues are infiltrated by enormous and appalling growths of micrococci. The poisonous ichor or ptomaine, the chemical resultant of the decomposition induced by the proliferating micro-organisms, is produced in quantities measured only by the activity of the growths of the micro-organisms, and is absorbed rapidly into the blood, and in such amount that but a few hours are needed for such a degree of blood poisoning to be effected that death is the result.

The case in question is seen to have had, in an unusual degree, all the conditions needful for the development of the greatest activity of invading micro-organisms—general resisting power at a low ebb; local tissue resisting power undermined by previous disease; traumatism great and prolonged; a hospital atmosphere likely to contain active germs. It is obvious that, in other cases in which less favoring conditions exist, every gradation, both of the local and general toxic manifestation, may be produced, so that in slight irritation and transient fever, in phlegmonous inflammations, early bounded by the formation of a wall of granulation tissue, in diffuse inflammation with spreading gangrene and advancing venous thrombosis, as well as in

the instance in which profound and rapid general intoxication is produced, with but slight local symptoms, we have an expression of the result of the same disturbing agent. While it is true that the development of these effects does not necessarily depend upon the presence of veins in the wounds thus attacked, yet a frequent connection between veins and the more severe grades of this tissue poisoning results from the readiness with which the connective tissue which ensheaths the veins permits the progressive invasion of micro-organisms, and from the fact that the resulting periphlebitis determines the formation of coagula in the involved vein which, in their turn, are likely to be speedily invaded by micro-organisms and become converted into poison depots, from which ptomaines, pus, and emboli are discharged directly into the circulation.

The question whether the application of a ligature to a vein is in itself the source of any additional hazard in any given case becomes susceptible of a more definite answer in the light of the more definite knowledge to which we have attained as to the pathology of the disturbances which complicate wounds. It has been seen to how different a conclusion a simple appeal to experience has led different observers, these conclusions varying from the extreme represented by Gross, that "the danger of ligating veins is in great degree if not entirely unfounded," to that represented by Chassaignac, that "ligation is one of the most dangerous operations of surgery." A more satisfactory result will be reached by an analysis of the particular conditions which the presence of a ligature upon a vein introduces into a wound, and by a consideration of the effects of such conditions upon its repair.

The introduction of the antiseptic animal ligature has modified so greatly the conditions which attend a ligature, in those cases in which it is used, that a discussion of the effects of the ligature demands a separate consideration of the simple unprepared thread and of the antiseptic animal ligature.

The doctrine that the tunics of a vein possess a special intolerance, that renders them liable to destructive inflammation more quickly and upon less irritation than other tissues, has received abundant refutation, and deserves mention simply as a matter of historical interest.

The effect of the mere constriction of the vessel by the ligature does not introduce new dangers into the wound. What these effects are, the use of antiseptic ligatures has enabled us to determine, and their discussion will be in order more particularly in connection with the consideration of the effects of such ligatures. It is, therefore, among the indirect effects of a ligature that conditions of importance, if there be any, are to be found. These indirect effects are purely those produced by the prolonged sojourn of the ligature in the tissues. Whenever the traditional ligature is applied, the constricting thread is an irritating foreign body in the wound, and invariably excites along its track an inflammation which persists until its removal is permitted by the division, by ulceration, of the walls of the constricted vein—a period of time extending upon an average from one to two weeks, according to the size of the vein. By preventing union by first intention, the ligature favors the entrance and development of atmospheric germs during the entire time that it keeps the wound open; and, saturated with the secretions of the suppurating sinus which it creates, it becomes the best of mediums for transmitting micro-organisms to the deepest part of the wound. The irritation of its presence puts an additional strain upon the resisting power of the tissues among which it lies, and to this extent lessens their ability to resist the invasion of the micro-organisms that may at any time find access to them.

The result of a failure of the tissues to resist such invasion of micro-organisms has already been dwelt upon, and the rela-

tion of cause and effect which they bear to diffuse periphlebitis and to septicæmia shown.

The conditions thus enumerated which attend the presence of an ordinary ligature, when viewed in the light of present knowledge as to the conditions by which wound disturbances are caused, certainly justify a dread of ligation as a hæmostatic agent in venous hæmorrhage, and make more emphatic the cautions as to its use. That in the great majority of cases the amount of disturbance resulting from the ligature should be limited to a circumscribed inflammation which simply mats together the tissues adjacent to the ligature, is but another evidence of the extent of the natural resisting power inherent in healthy living tissues. It is in those cases in which defects of resisting power exists, as notably in tissues whose nutrition has been interfered with by the varicosity of their veins, that the full effects of the conditions determined by the ligature would be developed.

But these considerations as to the source of wound disturbance, and their relation to serious complications after vein wounds, show the importance of eliminating them, not only in cases where veins already diseased exist, but also in all cases in which vein wounds demand special means for the control of hæmorrhage. The importance of protecting such wounds from further irritation, and from becoming the seat of multiplying micro-organisms, makes of great importance the search for a substitute for the ordinary ligature.

The acupressure of Simpson and the forcipressure of Péan both present great advantages over the common ligature as methods for controlling venous hæmorrhage, and few conditions will be found in which one or other of them may not be substituted for the ligature. The retention of the compressing needle or forceps is rarely necessary for a longer period than a few hours. Their smooth metallic surfaces do not irritate the wound, and their early withdrawal removes any obstacle to union by first intention that they might possibly have caused during their residence in the wound. In my paper of last year, already referred to, I reported a case in which permanent closure of a lateral wound in the internal jugular vein was accomplished by the application of a hæmostatic forceps, and its retention for a little more than twenty-four hours. In most cases, as in wounds of veins in the axilla or in the neck, in operations in those regions I have been able to remove them in a much shorter time.

In dealing with wounded veins, as acupressure needles and hæmostatic forceps excel the ordinary ligatures, so they, in turn, are excelled by the animal ligature and the antiseptic methods by which, with a perfect hæmostatic, easily and universally applicable, that provokes no irritation by its presence in the tissues, and that is spontaneously removed by absorption when no longer needed, security is also guaranteed against the access of micro-organisms that might disturb repair. By the use of the antiseptic animal ligature it becomes possible to avoid the sources of disturbance that have thus far been recognized in wounds involving veins, and thus to banish almost completely inflammatory and septicæmic complications from the phenomena that attend the ligation of veins.

But one possible objection presents itself to the use of an unirritating absorbable thread—viz., that its application may not be sufficient to provoke the effusion of the amount of plastic material necessary for securing the permanent adhesion of the vein walls at the point of constriction. Such an objection, however, has not thus far been supported by clinical experience. In connection with this, experience and experimental inquiry into the method by which obliteration of a vein is accomplished without the aid of a thrombus or of an irritating ligature would be of importance. For the purpose of such a study I made a number of experiments during the past year upon goats. These

experiments included three ligations of the internal jugular vein and two of the femoral vein. I was assisted in them by my friends, Drs. Fowler, J. H. Hunt, and J. E. Pilcher. Antiseptic catgut was used as the ligature in each, and the operation was done with antiseptic precautions. Union by first intention of the operation wound was secured in each instance. As the result of these operations, I secured specimens illustrating the condition of repair upon the second, fourth, ninth, fourteenth, and twenty-fourth days after ligation. These specimens were prepared for microscopical examination by Dr. Hunt, who made sections of the frozen fresh specimens, which were then stained with hæmatoxylin and eosine, and mounted in damar. In the interpretation of these preparations I have been able to obtain the skilled opinion of Dr. E. O. Shakespeare, of Philadelphia, who finds that in them the tissue cells of the tunica interna are seen to have undergone marked proliferation, the activity of this proliferation being greater as the point where the vein walls are constricted and approximated by the ligature is approached. By the accumulation and confluence of the mass of cells in the cul-de-sac, formed by the vein constriction, obliteration of the lumen of the vein is accomplished, this obliteration being perfected and made permanent by the subsequent extension of capillaries into it, and its transformation into connective tissue. Reference to these experiments, together with diagrams illustrating this proliferation of the tunica interna, will be found in a report of the lecture of Dr. Shakespeare, on "Inflammation in the Blood-vessels," delivered before the College of Physicians of Philadelphia, 1882, and published in the "Medical News," May 20, 1882, p. 539.

In none of these experiments did a thrombus form on either side of the ligature except in one case, in which, after having applied one ligature, I applied a second one to the swollen vein above, a little more than an inch distant. The part of the vein between the two ligatures having been left filled with blood, I thus obtained a thrombus. This specimen was removed on the ninth day. It seemed to illustrate the conditions of repair in the absence of a clot on the one side of the ligature, and in its presence on the other side. On this latter side the clot has simply seemed to be an unirritating injecting material by which the vein is distended and the study of the conditions presented by the vessel is facilitated, without otherwise modifying the character of the reparative process. The clot plays here, as in any other wound in which blood has been effused, and in which it has been protected from the access of destructive micro-organisms, simply the part of an unirritating foreign substance, mechanically distending the parts among which it is diffused, until it shall be invaded and appropriated by active cells from the adjacent tissue.

The ligatures still remained unchanged in all the specimens, the chromic gut, which was used in the first two experiments, and the long-kept carbolized gut (three years in carbolized oil), which was used in the last three experiments, not being readily acted upon by the tissues. Though the ligatures were thus made less absorbable, the tissues in which they were imbedded showed no irritation from their presence.

A plain conclusion from these considerations as to the character of the process determined by the application of a ligature to a vein, is that the obliteration of the lumen of the vessel is a secondary effect of reparative changes which have, as their first object, the restoration of functions in parts whose nutrition has been disturbed by the original application of the ligature. The simple fact is that the agent which has disturbed the nutrition of the tunica interna, and provoked a more active metamorphosis and proliferation of its cell elements, has at the same time held the vein walls in coaptation until the confluence of the plastic material from the constricted vein walls has be-

come sufficient in amount and tenacity to permanently unite them together. Essentially, the process is that of the formation of a cicatrix, and in its course the ligature plays the same part as does the suture in ordinary wounds—that of maintaining coaptation of the wounded structures until firm adhesion is secured. We see in this, also, the same process as that by which a simple lateral slit in the vein wall may be repaired without obstruction to the current of blood through the vessel, the edges of the slit themselves furnishing the material for its repair, the amount of which material, if only further irritation or traumatism be withheld, being strictly limited to the reparative needs of the injured structures.

These conclusions as to the process of repair after ligation of veins with unirritating ligatures find an important practical application in the consideration of the propriety of substituting a lateral ligature, or a lateral suture, for ligatures encircling the entire vessel in the treatment of wounds involving but a portion of the side walls of a great vein.

It will be remembered how positive was the condemnation of the lateral ligature expressed both by Professor S. D. Gross and by Professor S. W. Gross in the Philadelphia discussion. I find that Malgaigne (*"Médecine opératoire,"* ed. 1861, p. 114) also strongly condemns it, saying that "the lateral ligature will be an operation for ever to be condemned," and that "for very extensive wounds of venous trunks, where compression is insufficient, the *only* resource is the ordinary ligature." Malgaigne's objection, however, was founded on the erroneous idea that permanent hæmostasis after a vein wound depended upon the formation of a clot sufficient to occlude the entire lumen of the wounded vessel, and that, inasmuch as the lateral ligatures in some cases might fail to provoke the formation of such a clot, in such cases, where the ligature came away, secondary hæmorrhage would be inevitable.

The objection of Professor Gross is based upon the statistical statement that, of thirteen instances in which the lateral ligature had been applied, four proved fatal from secondary hæmorrhage, a source of danger of rare occurrence when a vein is ligated in its continuity. Such a record of disasters, in his opinion, outweighs any advantages that might be supposed to be gained by lateral ligatures, and makes its use unjustifiable.

It is to be borne in mind, however, that this record of disasters is a record of results from the use of the ordinary ligature. Reference to what has already been said as to the conditions which the use of such ligature introduces into the repair of a wounded vein will be found to give ample explanation of the frequency of secondary hæmorrhage after its use as a lateral ligature. The introduction of the antiseptic animal ligature, however, which may be cut short, and over which speedy union of the wound by first intention may be secured, places the subject of lateral ligature upon an entirely different basis. The tissues of the puckered side wall of the vein, where they are grasped by the ligature, are placed in the same condition as that already described as characterizing veins ligated in their continuity. No thrombosis is required, nor formed, by its insufficiency or its disintegration, to become a source of danger. There is no ulcerative process to extend unduly and to leave an opening in the vein wall when the ligature comes away. That the process of the formation and complete organization of the plastic material that fills in and effaces the irregularity produced by the application of the ligature should proceed undisturbed to its conclusion, demands simply that the general precautions for securing wound repairs are observed. The ligature acts as an unirritating re-enforcement that prevents the rupture of this new tissue during the yielding period of its history, and itself finally is disintegrated and is removed in the ordinary tissue changes of the part. Practiced with the antiseptic animal

ligature, lateral ligature, therefore, promises to be a justifiable and valuable means of treatment in wounds of the lateral walls of veins.

Lateral suture suggests itself as a resource in long linear wounds of the side walls of large veins. It would be simply a modification of the lateral ligature, and the same considerations would be applicable to it. I believe it to be practicable, and can conceive of conditions in which it would be a resource of great value.

Dr. POST remarked, concerning the ligation of veins in stumps after amputation, that he had been accustomed to do so without hesitation, and had not known any injurious consequences to follow. He had had one case in which he tied the primitive carotid artery for a large telangiectasis involving one side of the face. The patient died with symptoms of pyæmia. Although the jugular vein was not exposed, there was found at the autopsy thrombosis of that vessel and embolic inflammation of the lung. The vein also contained a phlebolite. He had also met with one fatal case of phlebitis following the use of pins in the treatment of varicose veins of the thigh.

Dr. GEESTER had applied the lateral ligature to the internal jugular vein in a case of multiple lymphoma of the neck. A row of catgut ligatures was applied to a longitudinal slit, and primary union followed the operation. He had also ligated the internal jugular vein in the course of excision of tumors of the neck in four instances. In some of these cases he applied simply a double ligature. In two instances, however, he was obliged to excise considerable portions of the vessel, and in one case death followed excision very shortly. The case was one of those where it is impossible to determine whether death was caused by incipient acute septicæmia or shock. Post mortem was made, but it did not reveal any positive evidence as to the cause of death. The central portion of the vein did not show any septic changes which could serve to explain the termination of the case.

In one case he had excised a very large venous plexus, situated near the scroto-femoral fold, mainly on the inner surface of the thigh, in a powerful young baker, who was prevented from attending to his daily business on account of the severe pain which the growth produced. It was a convolution of varicose veins, some of them very large, covering an area of about ten square inches. In that case he removed the entire mass, and proceeded as in the excision of a very vascular tumor, applying double ligatures, about sixty in number, and cutting the vessels between them. Some of the branches of the vessels penetrated through the fascia into the muscular structure, and were removed with portions of connective tissue and of muscle *en masse*. Union by first intention occurred in this case, and no further trouble was experienced. The chromicized catgut ligature was employed.

Dr. LANGER referred to a case already reported to the society, in which he applied the lateral ligature to the internal jugular vein, accidentally opened in the attempt to tie the common carotid artery for secondary hæmorrhage. In that instance air entered the vein. The ligature used was antiseptic silk. Recovery took place, and he subsequently presented the patient to the society.

VESICAL CALCULUS WITH A PIECE OF SILVER WIRE FOR A NUCLEUS.—Dr. J. C. HUTCHISON presented a vesical calculus removed from a boy fifteen years of age, and upon whom he had operated ten years ago for stone in the bladder. The first operation was that of median lithotomy, in which he wounded the rectum; a rectal fistula followed, and continued up to the time of the second operation. He made several attempts to close the fistula, twice by inserting silver-wire sutures, two or three times by touching the margins of the fistulous opening

with nitric acid, but in all instances unsuccessfully. The last attempt to close the fistula by sutures was about a year and a half ago. The case was left under the charge of the house surgeon, who was requested to remove the sutures at a certain time, and he did so. The boy, however, was never comfortable after the operation, but always complained more or less of pain in the bladder. The urine continued to pass through the rectum, but the opening was very small. On the 1st of February last Dr. Hutchison examined the bladder very carefully with the sound, symptoms of stone having presented themselves, and detected a calculus. On the following day he performed the medio-bilateral operation, and found the stone adherent to the posterior part of the bladder so firmly that he was unable to detach it with his finger, but, by taking a piece of flexible wire and making a loop, he was able to remove it. On examining it, he found the nucleus was a piece of silver wire.

The interesting features in the case were, first, the wound of the rectum, not a common accident in lithotomy; second, the difficulty in closing the fistula; third, the accident of dropping a suture into the bladder which formed the nucleus of the calculus; fourth, the difficulty of detaching the stone from the wall of the bladder at the time of the operation. After the last operation the perineal wound was kept open for twelve days, and the edges of the fistula were again touched with nitric acid. The wound was kept open by introducing a catheter through it, allowing the tip of the instrument to remain just in the neck of the bladder, pushing it forward occasionally to withdraw the urine. This was done with the hope that the fistula might close, and he was of the opinion that union had taken place.

Dr. Post mentioned that Dr. Kearny Rogers operated a large number of times for vesical calculus, and frequently wounded the rectum, but no bad results followed in any of his cases.

Dr. BRIDDON remarked that wounding the rectum was not so frequent as was generally supposed. It had occurred once to him in eighteen lithotomies.

The PRESIDENT remarked that wounding of the rectum with the median operation was quite unusual. He had operated by the median operation some thirty-four or thirty-six times, and had never had an accident of that kind.

Dr. HUTCHISON remarked that this was the only case in which he had performed the median operation.

OSTEO-SARCOMA OF THE THIGH.—Dr. Post remarked that an interesting feature in the case which he reported at the last meeting was that a week after the operation there was an active pulsation in the femoral artery from the groin downward to the point where the vessel bifurcates. Below that point, the patient's limb being very thin, he was able to trace the vessel distinctly as a hard cord, nearly as large as the little finger, and evidently filled with a coagulum.

A STATED meeting was held March 13, 1883, T. M. MARKOE, M. D., President, in the chair.

SUTURING OF THE DIVIDED ENDS OF EXTENSOR TENDONS IN THE FOREARM.—Dr. F. LANGE presented a lady patient who, about two months ago, fell from a considerable height, and struck against a china umbrella stand, cutting the tendons of the extensor muscles of the left forearm. He saw the patient two weeks afterward, when the wound was almost healed, and there was extensor paralysis involving the third and fourth fingers, only the last two joints moving through the action of the interossei. About four weeks ago Dr. Lange made a longitudinal incision, and found that three of the extensor tendons had been divided, namely, those belonging to the third and fourth fingers, and to the index finger. The extensor indicis proprius was not injured, for the action of the index existed.

The divided tendons of the extensors were separated to a distance of almost one inch and a half. They were brought together and sutured with antiseptic silk. The hand was then put in a position of superextension, and an antiseptic dressing applied. The sutures were removed at the end of one week. The result was that the movements of the fingers could already be quite satisfactorily performed, and it was probable that improvement would still continue.

SUPRA-CONDYLOID FRACTURE OF THE HUMERUS, WITH INJURY OF THE MEDIAN NERVE. OPERATION.—Dr. LANGE also presented a girl eight years old, who, in August last, received a supra-condyloid fracture of the left humerus from a fall of three or four feet, and striking the arm against a beam. A dressing was applied, which she wore for some time, but during the third week, according to the mother's statement, painful contraction of the fingers and wrist occurred. At that time forcible tractions seemed to have been made, but the pain did not cease, neither the contraction, but, on the contrary, the hand became more and more contracted and paralyzed, and finally quite useless. From the time of the receipt of the injury she had complained of some pain at the site of the fracture. She came to New York about the middle of December, at which time the wrist and fingers were flexed to their utmost, and the movements of the fingers were very slight indeed. Only slight movement of the first phalanges and of the wrist could be made. Every attempt to stretch the parts was followed by intense pain, especially at the site of the fracture, where there could be distinctly felt a sharp protruding edge of bone, and between the fragments there seemed to be a sensitive cord which Dr. Lange thought might be the median nerve, but this subsequently proved to be an erroneous assumption. The movements in the elbow joint were restricted to an angle of about twenty degrees. There was paralysis of sensibility in the region of the median and the radial nerves and entire absence of electric irritability. Dr. Lange recommended at first electricity, massage, and active and passive movements. This treatment was given for about six weeks, at first with some marked success. After several weeks, however, the progress ceased, and the pain at the site of the fracture persisted. Dr. Lange then proposed an operation, assuming that the nerve at the point of fracture was irritated by the callous and adhesions, and at that time Dr. Sands saw the patient in consultation and approved of the proposed procedure. About four weeks ago Dr. Lange cut down on the inside of the elbow joint against the protruding fragment, and found the following relations: The median nerve ran in front of the sharp edge of the bone in an angle, and at that point was somewhat flattened. Above that point it was somewhat swollen and thickened. The spindle-like swelling which he felt before the operation was a mass of muscular fiber belonging to the brachialis internus. He loosened the nerve, excised the protruding fragment of bone, and since that time there had been decided improvement, both with regard to the facility of movements of the fingers and the use of the hand. The strength of the muscles which are supplied by the median nerve had not improved very much, and yet it seemed as if the cramped condition which existed in the flexor muscles was steadily decreasing. It seemed, also, that the extensor muscles had become more active since the operation. There was one interesting point, namely, that since the operation an entirely different and more normal form of nail was growing, and there were ridges on all of the nails alike, marking the parts of the nail before the operation from those after it. The color and temperature of the skin had also markedly improved. Having been of a pale bluish before the operation, it was now of a more rosy tint. The temperature of the hand had become normal.

Dr. C. T. POORE then read a paper entitled *SOME EXPERIENCE IN EXCISION OF THE HIP JOINT*. I do not think that I have anything new to offer in regard to excision of the hip joint. The object of this paper is simply to call out discussion.

As far as my experience goes, suppurative disease of this joint has its origin in an osteitis, or osteomyelitis, as it is sometimes called, of the head of the bone, the articular cavity being involved secondarily. This paper is based on the experience in eighteen cases of excision occurring among the poorer classes and in hospital practice. They are not, therefore, to be compared with cases occurring among the better classes.

Ten cases occurred in girls and eight in boys; the youngest was two and a half, the oldest was fourteen years of age. The disease had lasted for from two to sixteen years. Many of the patients had been under strict mechanical treatment from one to four years without any effect on the course of the disease. Abscesses continued to form and discharge, so that in not a few patients the thigh and gluteal region were riddled with openings, from which pus continually flowed, while in others only one opening had formed. Excision was performed in all cases in the same way, with a long incision over the trochanter major. The tissues were separated from the bone and the head was removed, in thirteen cases above the trochanter minor, and in five below that point; in four cases, after some months the end of the femur was excised.

The pathological conditions underlying the external symptoms mentioned above were as follows: In seven cases the disease was confined to the head of the bone, the shaft appearing healthy. In all these cases the cartilage had entirely disappeared, and in most the head was represented by tubercles, or lay loose in the cavity of the acetabulum. The shaft was diseased in eleven cases. By this I mean that the central cavity was enlarged at the expense of the compact tissue, so as in many cases to admit the finger. The external shell had in many places a worm-eaten appearance. The bone was of dark color, and so soft that a probe could be easily made to perforate it. In a few cases the cavity was filled with pus. The periosteum did not appear much thickened, but was easily separated from the shaft. The floor of the acetabulum was more or less diseased in all of the cases. It was perforated in four. It was extensively diseased in its upper and posterior border in nine; in two cases I have seen a perforation of the upper wall opening on to the dorsum of the ilium, the external edge forming a bridge over it. In one case there was extensive disease of the pelvic bones. In short, they were all cases of advanced disease, and the pathological conditions such as, in other joints, would call for excision.

The result in these eighteen cases was as follows: Two are still in the hospital, leaving sixteen to be accounted for. Of these, eleven died and five recovered—about thirty-two per cent. The causes of death were, from pure exhaustion, one; tubercular meningitis, one; septicæmia, one; phthisis, one; amyloid degeneration, seven. In one of these cases the wound had entirely closed at the time of death. Death did not take place in these cases for some time after the operation, varying from two months to four years. The immediate effect of the excision in these cases was an improvement in all respects. The patients were free from pain, increased in flesh, had normal temperature, and in most of them were able to be about. But the wound never entirely closed except in one case. Sometimes only a small sinus was left. After a time, an examination with the probe or finger revealed the upper end of the femur bare and rough, unhealthy granulations growing from its cavity, and an examination of the abdomen in many showed enlargement of the liver and disease of the kidneys. In some cases the end of the femur was re-excised, and the cut surface exhibited the same unhealthy condition. These patients died, not from, but in spite

of the operation. Of the five patients in whom recovery took place—and by this I mean that the wound entirely closed—no sinus remained open, and the child had use of the limb. The disease had existed six years in one, three years in one, and two years in three cases. In all these patients the family history was comparatively good. In two cases, at the time of the operation, there was enlargement of the liver. In one of these, albumin in large quantity was present in the urine, and the patient had two quite profuse hæmorrhages from the lungs. Section was made one inch below the trochanter minor on account of profound disease of the shaft, yet recovery took place. In the other case the disease was confined to the head of the bone.

In regard to the permanency of the cure, one case was heard from five years after leaving the hospital. He was going about, and had good use of the limb. One I examined six years after. He was well, and had been following the occupation of an express driver. One was seen eighteen months after his discharge, and was well. The other two cases I have lost all trace of.

In regard to the amount of shortening in these cases, it varied with the duration of the disease, its extent, and the point of section. In four cases it was as follows: Three fourths of an inch; one and one fourth at time of discharge, and one and three fourths eighteen months later; seven inches five years after leaving the hospital. In one case, two inches.

The elements going to make the shortening after excision of the hip joint are, first, the amount of bone actually removed; secondly, the amount of atrophy of the whole limb from disease and disuse, and thereby the amount of stretching of the band holding the end of the bone to the pelvis. Three of my cases walked well without either crutch or cane; one with seven inches shortening can not afford to keep himself provided with a high shoe, although he can bear his weight on the limb. He therefore uses a crutch.

In referring again to the cause of death, it will be noted that in all but two patients it was due to diseases secondary in their nature, namely, amyloid degeneration, tubercular meningitis, and phthisis. The deaths from septicæmia and exhaustion were due, one to the operation, and one to the joint disease. All the patients having amyloid disease belonged to families having a marked tubercular diathesis. In some cases these changes in the abdominal organs came on early; others late, after suppuration had made its appearance. It would seem that, from a study of these cases, and others in which no operation had been done, there is a marked predisposition among children of tuberculous parents to become thus affected in the course of hip-joint disease. I have never seen a case that was not so connected, and it would seem that, the more profound the hereditary influence, the earlier these changes appear.

Two of the patients operated upon had at the time of excision marked enlargement of the liver, and one had albumin in large degree in her urine, yet both recovered; and, on examination made five years later, in one the liver was found of normal size; the albumin disappeared shortly after the operation.

I have never seen a true dislocation of the head of this bone on to the dorsum of the ilium.

The questions that naturally suggest themselves from a study of these cases are: first, was a cure by mechanical and expectant treatment probable; and, secondly, what are the indications for excision of the hip joint.

In regard to the first, I am clearly of the opinion that a spontaneous cure was not probable. The fact that, in those cases that proved fatal after excision, the patients improved in all respects for a time, varying from six months to over a year, and that they finally died of secondary disease, would seem to corroborate that opinion. I think that an earlier operation would have diminished this rate of mortality.

In regard to the second question, What are the indications for incision? I think that it is more difficult to lay down any rules. In cases giving a good family history, much can be done by mechanical treatment, and I do not think that an early operation is called for. But in the class of patients belonging to families of marked tubercular ancestry, and in hospital practice, I think that the question of excision should be considered soon after abscesses have made their appearance, as there seems to be a kind of malignancy in these cases.

The presence of amyloid changes is not a bar to recovery, but is a very serious complication.

(To be concluded.)

Letters to the Editor.

"BOYCOTTING" BEGUN.

31 WEST THIRTY-SIXTH STREET,
NEW YORK, April 17, 1883.

To the Editor of the New York Medical Journal:

SIR: On the 19th of February last a gentleman from a city in this State called upon me and placed his daughter, suffering from Pott's disease of the spine, under my care. At the end of a few days, and after the apparatus had been adjusted and full instructions as to treatment, etc., had been given, the patient returned to her home.

Not long after her return she was attacked with pneumonia, and for several weeks she was unable to wear the support. Quite recently some of the symptoms became obscure, and the family physician (a homœopath), being unable to decide whether the patient should wear the apparatus, wrote me on two or three occasions asking some questions. I answered these letters. Then came a request from the father of the child that I should visit the patient. To this I consented. A few days ago I visited her, and afterward conferred with the family physician and a prominent surgeon of the place (a "regular"). My diagnosis was accepted, and all suggestions as to treatment were, I believe, adopted by the family physician.

Three days after my return I received a letter from an old and prominent member of the profession in the city I had visited. I quote from this letter, omitting names for the reason that, to this extent, I regard it as a privileged communication. My correspondent, after referring to my visit and the gentleman I had met, says:

"I am sorry to find you follow the new code, and are now doing all, it appears, you are able to injure an honorable profession and make the getting their daily bread even more difficult to many of its members by holding up the hands of quacks here, and, presumably, elsewhere. At the February meeting of the ——— County Medical Society the society voted 22 or 3 to 7 to stand by the code of the American Medical Association, and repudiated the actions of the State society.

"We will boycott all doctors here or elsewhere who pursue a different course, and, if we can't find loyal men in New York to send our friends and patients to when we need counsel, we will send them to Boston and Philadelphia.

"Respectfully yours,

"———, M. D."

I would not presume to publish or comment upon my friend's letter were it not that his threat is a general one. As such I feel that I have a right to place it upon record.

My personal relations to the case, it seems to me, need no explanation. But, as my friend takes it for granted that there is something wrong, I may be pardoned for saying that I went to visit my own patient. I was responsible to the parents of the child for the treatment of a chronic disease. The patient needed my personal attention. At the same time the experience of the family physician did not enable him to decide upon the value of certain symptoms, which lack of experience he thought I might be able to supply. My analysis of the symp-

toms aided the attendant, enabled him to direct the treatment more intelligently, and brought comfort alike to the patient and to her anxious parents. I would like to ask my correspondent: Upon what grounds could I have declined to visit the patient and confer with the family physician? Could I have advanced in any way the interest of science, of humanity, or of true progress by declining? On the contrary, was it not my duty, in every sense, to afford the patient the benefit of my experience?

Would it not also be pertinent for me to ask my friend if, in "boycotting" those who differ from him in his interpretation of medical ethics, he does not convict himself of even a greater error than that which has so often been attributed to homœopaths alone? Is there any more mistaken dogma than one which excludes and threatens? As an illustration of the absurd position of my correspondent, I might say, if I were called upon to meet him in consultation, that I should have as good grounds for declining to meet him as those usually assigned for declining to meet an "irregular"—whose "exclusive dogma," after all, does not "boycott" those who differ on ethical points, and whose position, though far from meeting my approval, is not sustained by threats.

There is one point which strikes me very forcibly in my correspondent's letter. It has been the custom of certain opponents of the "new code" to ascribe to "specialists" alone a selfish and moneyed view of these "irregular" consultations. In this letter we find, from a prominent general practitioner, a frank statement that it is a matter of self-interest which sustains him in his position: for he places the matter squarely upon the "daily bread" basis, and by "boycotting" he threatens to take from all those who do not think as he does, so far as he is able, the means by which "daily bread" is gained in the profession.

I wish to say to my friend that I have no sympathy whatever for any school of medicine save the one founded upon the broad basis of science and humanity. But, while there are, as exist to-day, different schools which are recognized in law, while there are honest differences of opinion, while there are so many obstacles in the way of educating public opinion, there is, it seems to me, only one course. We should lay aside all prejudice and bigotry. The school of science and humanity should be liberal. Its members should ignore petty differences. They should be prepared to meet in consultation, when necessary, all who need their services, refusing to meet those only of any school whose education, associations, and reputations make them unfit for the company of gentlemen.

I have occupied more of your space than I intended. The subject, however, is an important one, and, though I know too well that my influence in the matter will count for little enough, I have availed myself of the text which my friend gives me to extend to him, through your columns, my criticism upon his conduct and position.

Yours faithfully,

NEWTON M. SHAFER.

Miscellany.

THE DEVELOPMENT OF STUMPS BY THE USE OF ARTIFICIAL LIMBS.—The impression seems to prevail to some extent among physicians that an artificial limb should not be worn after an amputation until the stump has had time to "harden," and, with this idea, patients are advised to defer the purchase of a limb frequently for months after the immediate effects of the amputation have entirely disappeared.

Undoubtedly there are many cases in which this advice is good, particularly in those of a strumous diathesis in whom an injury or abrasion may be productive of severe local lesions, and in those where amputation has been done in consequence of a necrosed condition of the bones. It is not this class, however, to which reference is made, but rather to those in which amputation is rendered necessary by an injury occurring when the individual is in full health, as in cases of gunshot wounds, and in the almost daily and by far too frequent accidents on the steam- and horse-railroad tracks.

It may be safely laid down as a rule that the sooner after an amputation an artificial limb is applied, the better it will be for the development of the stump, and the preservation of the symmetry and health of the sound limb. Especially does this seem to apply to cases occurring in young persons, in whom the stump is apt not only to fail in development proportionate to the growth of the individual, but to become atrophied and flabby from disuse.

In a recent conversation with Mr. A. A. Marks, manufacturer of artificial limbs in this city, attention was called to this matter, and the following case was cited in support of the theory:

FIG. 1.

The subject of the accompanying illustration, when but eight years of age, was furnished with one of Mr. Marks's artificial legs, which has been lengthened, enlarged, or replaced by Mr. Marks as demanded by the increased size of the wearer.

The result of this early application of an artificial leg is seen in the healthy development of the stump, which nearly equals in size the corresponding part of the sound limb. In street dress one would hardly recognize the one-legged gymnast whose feats of strength and whose agility have given a world-wide reputation to "Stewart Dare," as he is known in public. When off the stage and in street attire, his easy, graceful walk gives very little evidence of an artificial leg, which is due in part to the perfect adaptation of the socket to the stump, and in part to the flexible rubber foot (invented by Mr. Marks), whose

FIG. 2.

action so closely simulates that of the natural foot, and does away so thoroughly with the tell-tale "thud" which always accompanies the use of the ordinary artificial leg, that one would hardly suspect that the individual under observation had been subjected to an amputation.

THE ASSOCIATION TO PREVENT THE RE-ENACTMENT OF THE OLD CODE.—On Friday evening, the 20th inst., the "Association for Preventing the Re-enactment in the State of New York of the Present Code of Ethics of the American Medical Association" was organized at a meeting held at the house of Dr. Jacobi, being an adjourned meeting of those opponents of the old code who met at the same place a fortnight before. In the absence of the president, Dr. Alfred C. Post, Dr. S. O. Van der Poel presided. Among those present were Dr. Fordyce Barker, Dr. A. Jacobi, Dr. William H. Draper, Dr. Thomas Addis Emmet, Dr. Charles E. Hackley, Dr. Charles Carroll Lee, Dr. Alfred L. Loomis, Dr. C. R. Agnew, Dr. D. B. St. John Roosa, Dr. James L. Little, Dr. Edward H. Parker, of Poughkeepsie, Dr. Henry G. Piffard, and about fifty other gentlemen. A plan of organization was adopted, and a form of address to the profession throughout the State was settled upon. The latter will be found in another article.

AN APPEAL TO THE MEDICAL PROFESSION OF THE STATE OF NEW YORK.—At the same meeting the following address to the medical profession of the State of New York was adopted, and ordered to be issued signed by the President and the Committee of Fifteen:

"When a considerable number of the representatives of a learned and liberal profession honestly believe that the rules by which their relations to their colleagues and to the public have hitherto been regulated have been injurious to the profession and to the community, it is clearly their right and their duty to labor for the abolition of such rules, and to state the reasons why they should no longer be enforced.

"The Code of Ethics of the American Medical Association which is now in force is identical with that which was in force in the Medical Society of the State of New York, and which was abolished at the annual meeting of that society in February, 1882. It appears, from the proceedings which led to the abolition of the code in the State of New York, that there had been a gradually increasing conviction among its members that some of the provisions of the code were arbitrary and illiberal, and that a larger liberty should be granted the members of the society in the performance of their professional duties. After a full discussion of the subject, a vote of the society was taken, and, by a constitutional majority, the old code was abolished, and a new one was enacted in its place. Among those who voted for the substitution of the new code for the old one were many members who preferred the abolition of a specific ethical code, as unnecessary for the guidance of an honorable and learned profession. But the members who took this view of the subject were willing to unite with those who were less radical than themselves, in order to secure the abandonment of the most obnoxious features of the old code. At the annual meeting of the society in February, 1883, a strong effort was made by the advocates of the old code to undo the work of the previous year and to re-establish in this State the code of the American Medical Association. For this purpose no exertions were spared to secure the election of delegates who were in favor of the proposed retrograde movement. But the efforts which were then made failed to secure the votes of even a majority of the members of the society, a two-thirds vote being necessary.

"It is well known that a strong effort is now being made, even by coercive measures, to secure in advance such a representation at the meeting of the society in 1884 as will undo the work which was done in 1882 and 1883. Believing that such action would be injurious to the honor, dignity, and usefulness of the profession, and to the best interests of the community, we earnestly entreat the members of the profession to give the subject their serious consideration, and to use all legitimate means to prevent the re-enactment of the present code of the American Medical Association by the Medical Society of the State of New York. It appears to us to be particularly important to preserve to each member of the profession perfect liberty to decide for himself how he shall act in order to secure the best interests of the sick and the honor of the profession.

"The arbitrary rules which have controlled, to so large an extent, the actions of medical men, and which were originally designed to defeat the efforts of irregular practitioners to gain influence with the community, have signally failed to accomplish the object in view. These rules have not commanded the respect of intelligent men in

other professions. They have been regarded as belonging to the same category as the rules by which the various trades-unions have infringed upon the individual liberty of their members, subjecting those who resisted the arbitrary action of the majority to the greatest indignities, pecuniary losses, and even personal sufferings and dangers. We call upon the members of the medical profession to unite with us in freeing the profession from this stigma, and in giving to all its members perfect liberty to practice their art in accordance with the dictates of their own consciences, and with the enlightened opinion of intelligent men who are engaged in other pursuits."

DR. FORDYCE BARKER ON THE CODE CONTROVERSY.—We give below a report which we believe to be substantially, and as near as possible verbally, correct of the remarks of Dr. Fordyce Barker, President of the New York Academy of Medicine, who had been invited to be present at the meeting of the "Association to Prevent the Re-enactment in the State of New York of the Present Code of Ethics of the American Medical Association," in response to a call from the Chair.

Dr. Barker said: Mr. President, I thank you for this opportunity to define my exact position in regard to the question which is now so disturbing the profession, not only of this city and State, but throughout the whole country. I have declined to become a member of your association, and I hope my reasons will be perfectly understood, even if not perfectly satisfactory, to every gentleman present. I am always willing to concede to every one else perfect tolerance of honest conviction, freedom of conscience, and liberty of action in all questions of moral duty, so far as they do not interfere with the rights of others, or our obligations to our profession and the public; and I claim, and shall always claim, the same right for myself as an individual. It has long been my conviction, as I have repeatedly expressed within a few years before large public meetings both in this city and elsewhere, in no equivocal terms, that the influence of the old code, as it has generally been understood, has not been useful to the profession as regards either its relations to the public or its influence on the conduct of its individual members in some important points relative to its ethical duties to those who seek for our professional assistance.

If, therefore, I have been misunderstood and misrepresented by some who stand prominent on both sides of the hot contest now going on, I do not feel that it is my fault, but accept it as my misfortune as an individual, and I wait in the full confidence that time will set me right. But, sinking all personal considerations, I think it important that all should understand the present status in relation to the unfortunate and deplorable contest now going on in the profession. Some four weeks since I had an interview with one of many valued friends who hold opinions different from my own in regard to the necessity and usefulness of the old code. One year ago the matter had come up before the Academy of Medicine in relation to the action of some of its delegates to the State Medical Society. Dr. Flint then expressed himself in strong terms against any discussion of the code or ethical questions in the Academy, and urged that such questions should be left to a sister society, the New York County Medical Society, where they properly belonged. I had no reason to believe that these views were not those also of all, with but one exception, who agreed with him in sentiment in regard to the old code. The result of our interview was an agreement on my part to reply to a letter which he would send me, and that he should make such use of my answer as he should deem best. This correspondence was sent by him to the "New York Medical Journal," and was published in its issue of March 24th. In my letter, the main point which I urged was that greater good could be secured by a discussion of the principles which underlie medical ethics, by the wise and good men of the profession who hold divergent views, in a spirit of candor and honest purpose, than by discussions in our medical societies, which almost necessarily involve personal feeling and the imputation of bad motives, and in which the wish to triumph by a majority of votes is stronger than the desire to convince. I have in my possession a letter from Dr. Flint expressing his great pleasure in receiving my letter, his belief that the letter would do great good, and informing me that he had sent it for publication to the editor of the "New York Medical Journal."

With but one exception, I never had the slightest reason to suspect

that the sentiments of this letter did not receive the approval of all those whose views in regard to the code were in accord with those of Dr. Flint, until yesterday noon. A gentleman then called upon me, whose countenance I recalled, but whose name I was compelled to ask. This gentleman asked me if I was aware that a circular had been privately sent to many members of the Academy, asking them to be present at the next meeting to vote for a resolution to instruct the Committee on Nominations not to recommend any one for election who was not in favor of the old code. He then stated that he himself had always been in favor of the old code, and that he had always voted in favor of it, both in the State and county medical societies, but that he could not join in such an underhand movement, as he knew that in certain instances terrorism had been resorted to with certain of the younger men who held positions in connection with some of our medical institutions. He was so disgusted with this method that he had determined not to attend the meeting. I had heard nothing before of such a movement, and could hardly believe that his statements were authentic, notwithstanding their circumstantiality. But I at once sent a note to Dr. Weir, the first Vice-President, telling him what I had heard, and begging him to be present, as, if this statement should be true, I wished to leave the chair and make my earnest protest against a movement which, in my judgment, would be ruinous to the Academy of Medicine.

During the afternoon I had convincing proof that what I had heard was authentic. It was late in the afternoon, and the question in my mind was what could be done to avert such a calamity for the Academy of Medicine. I saw no other way except to secure time for calm deliberation, time for passion and excitement to subside, for reason to recover its sway where madness now seemed to govern, and for wise counsels and sound judgment to control the action of the Academy. I therefore went to Dr. Flint (the Senior, I mean), and begged of him to make the motion promptly, that the by-laws be suspended, and that when the Academy adjourns, it be adjourned to the first Thursday in October. For reasons possibly satisfactory to himself, Dr. Flint positively refused to accede to my request.

Nothing more could be done by me except to preside at the meeting with the utmost impartiality, without exhibiting the least bias in favor of one side or the other. The attack was led, the motions were proposed, as you all know, by a most adroit machine politician, who has the fluent faculty of forcible expression, often more effective in excited assemblies than calm persuasion and sound argument, who, whatever may be his other merits, can not claim to be a medical practitioner. You all know the vote by a packed meeting, some of whom were brought there by intimidation. I assert what I know to be true, and you all know the preamble and resolutions which were adopted.

Then came the climax. It was then moved that the vote be reconsidered, and that the motion for reconsideration be indefinitely postponed. The leader who made this motion had the unblushing effrontery to distinctly avow that the object of this motion was to "throttle" the Academy—"throttle" was the precise word that was used.

The ignorance, the folly, and the absurdity of this, as a specimen of parliamentary tactics, would have been ridiculous and laughable had it not been pitiable and deplorable. No such vote as this can "throttle" any corporate body in taking away its power of expressing its future will.

But such a vote may asphyxiate the Academy in another way. It may stop its growth by preventing the election of another Fellow, as it creates a new standard of requirement, not of character, not of scientific attainment, but of belief as to codes of ethics. Those who are suspected of not being sound on this question will be black-balled, and this bad example will inevitably be followed by the equally bad practice of black-balling those whose honest convictions lead them to believe that the old code is useful and necessary for our profession. Then follows the great danger, also, of withdrawal from membership of large numbers. The disgust and displeasure excited by the proceedings of the evening caused three of our prominent Fellows to at once offer their resignations. After the adjournment, another, one of our most valued and important officers, who had always supported the old code, announced to me his determination to resign both his office and

his membership. I am sure that all present would be surprised if I should give the number of those who to-day have expressed, either by note or in a personal interview, their intention of withdrawing from the Academy; but I do not think that you will be surprised when I assert that the number of these who were supporters of the old code is even greater than that of the advocates of the new code or of no code. No high-minded, honorable man, who respects himself or regards the interests of his profession, will support or even sanction a "rule or ruin" policy in a scientific body with the high aims of the New York Academy of Medicine.

For some years, the Academy of Medicine has carried on its work most harmoniously, and it has been most prosperous. Its scientific work has been most valuable, and excellent as to its quality. Its library has grown with wonderful rapidity, and its Journal and Circulating Department has been put on a good basis. Our most promising and best young men were rapidly coming in to fill up its numbers and increase our resources, and many of our prominent men, who have before been indifferent, were taking a warm interest and participating in its discussions and contributing papers. Many others, not of our profession, have contributed handsomely to add to our means of usefulness, thus showing their interest in our work, and their appreciation of the importance and usefulness of the Academy of Medicine, both to the profession and the public. And now a firebrand has been surreptitiously thrown into our midst. The resolutions passed were wholly unnecessary, utterly mischievous and useless, and could accomplish no possible good, either for the Academy as a body, or for its individual members, or in the advancement of any principle or cause. It was pure wickedness, manifestly instigated by the devil.

I will frankly avow that no one present could have been more disgusted and offended by the ways and methods of the leader in last evening's bad work than myself. Painful as it is to end the intimacy and break the friendship of more than twenty years, I can never forgive him for dragging his noble father from the pinnacle where his beautiful character and grand professional work had placed him down into the mire of medical politics.

After the pernicious resolutions of the evening had been adopted, I made a personal request that some one would make the same motion as I had begged Dr. Flint to make, and my motives were the same as in the first instance. But my purpose I have since learned was misunderstood, and the motion was not carried. I then stated that, under existing circumstances, I felt that I could not carry on the duties of the office successfully or satisfactorily to myself, and I therefore felt compelled to resign.

The motion was then renewed, and the Academy now stands adjourned to the first Thursday in October. I then withdrew my resignation.

And now, Mr. President and gentlemen, I take leave to say that while I believe I am in thorough accord with the sentiments expressed in your declaration, as I have heard it read this evening, my loyalty and allegiance still remain with the Academy of Medicine.

The question of the code is only a question of the day. The spirit of the age, its progressive intelligence, the marked growth of broad and liberal views, a better appreciation of the ethics which should govern the profession in its relations to the public, must inevitably result from the study of the principles which underlie all ethics, and will, it is my firm belief, lead to a speedy settlement of the questions which now so agitate and disturb the profession. I have that confidence in the profession to believe that they will be settled as they should be, within two or three years.

But the question as to the perpetuity and the usefulness of the Academy of Medicine is one of great importance, both to the profession and the public, for all time to come. I do not anticipate that in five months there will be any essential change in the views of individuals in regard to a code of ethics, but between now and October violent partisan feelings may subside, and all good and true and strong men will feel that the honor and standing of the profession are at stake, that the estimation in which the profession as a body is held by the public is involved in the decision whether it will support a purely scientific organization, and keep up the excellent library and reading-room which

have been, by the generous and noble contributions of some of our number, so successfully established. I hope that at our next meeting some common ground can be found upon which all can meet and unite in working together for such a purpose, that all side issues may be banished, and that all opportunity for the admission of anything but scientific work, and the growth of our library, may be forever barred.

[Throughout this address, Dr. Barker was listened to with the closest attention. He spoke with the utmost earnestness, and was frequently interrupted with applause.]

OPponents OF THE OLD CODE.—We have been asked to publish the following list of those who have signed a paper headed:

"We, the undersigned, are opposed to the present Code of Ethics of the American Medical Association, and approve of the use of all honorable means to prevent its re-enactment in the State of New York."

THE ETHICAL CRISIS.—"There is little doubt," says the "Medical Record," "that the activity displayed by those holding diverse views regarding the question of ethics is leading many who heretofore have given little thought to the matter to begin a careful examination of the subject for themselves. A series of commentaries by Dr. Austin Flint on the Code of the American Medical Association is in process of publication in the columns of our valued contemporary, the 'New York Medical Journal.' In his remarks concerning the portion of the code that relates to consultations, Dr. Flint claims that the 'exclusive dogma' clause of the code was directed not so much against the homoeopaths as against the steam doctors, or Thomsonians, etc. He further claims that the American code was not intended 'to interfere with the practice of medicine, under any circumstances, in the cause of humanity.' He says that 'the restrictions of the code are in no wise inconsistent with the demands of humanity in cases of emergency.' This view of the case is certainly a novel one, and one that, so far as we are aware, has never been taken by any of the organized bodies that have heretofore accepted this code. If this is the correct view, it is greatly to be regretted that Dr. Flint had not brought it to

the notice of the profession at an earlier date. Curiously enough, he goes on to say that 'a practice based on an exclusive dogma' is not a proper ground on which to refuse to 'meet practitioners in consultation.' 'Any physician has a right either to originate or adopt an exclusive dogma, however irrational or absurd it may be.' Dr. Flint hopes that the American Medical Association 'will adopt such modifications in the phraseology of this section as will place restrictions on consultations, not on the ground of doctrines or forms of belief, but on separation from and avowed antagonism to the medical profession.' If Dr. Flint would personally urge this matter on the attention of the association as its approaching meeting, we have little doubt that much could be effected in the way of restoring harmony in the profession. A much better and lasting solution of the question, however, would be arrived at if the association itself would rescind all formal codes, and simply urge the profession to establish such ethical regulations as local circumstances might render most expedient. If the American Medical Association would for the future strictly confine its deliberations to the consideration of purely scientific matters, science would be the gainer and propriety would lose nothing."

THE AMERICAN MEDICAL ASSOCIATION.—The thirty-fourth annual session will be held in Cleveland, O., on Tuesday, Wednesday, Thursday, and Friday, June 5, 6, 7, and 8, 1883. The officers of the sections are as follows: Practice of Medicine, Materia Medica, and Physiology—Dr. J. H. Hollister, Chicago, Chairman; Dr. J. G. Lee, Philadelphia, Secretary. Obstetrics and Diseases of Women and Children—Dr. J. K. Bartlett, Milwaukee, Chairman; Dr. G. A. Moses, St. Louis, Secretary. Surgery and Anatomy—Dr. W. F. Peck, Davenport, Iowa, Chairman; Dr. P. F. Eve, Nashville, Tenn., Secretary. State Medicine—Dr. Foster Pratt, Kalamazoo, Mich., Chairman; Dr. T. L. Neal, Dayton, O., Secretary. Ophthalmology, Otology, and Laryngology—Dr. A. W. Calhoun, Atlanta, Ga., Chairman; Dr. Carl Seier, Philadelphia, Secretary. Diseases of Children—Dr. R. F. Blount, Wabash, Ind., Chairman; Dr. J. H. Sears, Waco, Texas, Secretary. Oral and Dental Surgery—Dr. D. H. Goodwillie, New York, Chairman; Dr. T. W. Brophy, Chicago, Secretary.

The Secretary gives notice that a member desiring to read a paper before any section should forward the paper, or its title and information as to its length (not to exceed twenty minutes in reading), to the chairman of the Committee of Arrangements, Dr. X. C. Scott, 393 Euclid Avenue, Cleveland, at least one month before the meeting.

Action will be in order on the following proposed amendments to the constitution: 1. Offered by Dr. N. S. Smith, Dakota—"To provide for the admission to membership of two delegates from the Medical Bureau of the United States Indian Service, to be nominated by the Surgeon-in-Chief of that bureau, and approved by the Secretary of the Interior." 2. Offered by Dr. J. M. Toner, D. C.—"That the office of Permanent Secretary be vacated, and that the Nominating Committee hereafter annually nominate a secretary who will serve without compensation." 3. Offered by Dr. F. Pratt, Mich.—"That the law requiring the nominations for officers to be made from those members present at the annual meeting shall apply only to the President, Vice-Presidents, Chairmen and Secretaries of Sections, the Assistant Secretary, the Chairman of the Committee of Arrangements, and the Judicial Council." 4. Offered by Dr. J. M. Keller, Ark.—"To permit the holding of the annual meeting as late as the first Tuesday of September, if desirable." 5. Offered by Dr. J. H. Sears, Ark.—"That the Chairman and Secretary of each section may add any number of earnest workers to their sections, in addition to those named by the Nominating Committee, and that the Librarian be made a permanent officer." Action will also be in order on an amendment to the By-Laws offered by Dr. J. W. Smith, of Iowa: Art. II, Sec. 8. Permanent Members: strike out the words "but without the right of voting."

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.—The fifth annual meeting will be held in New York on Monday, Tuesday, and Wednesday, May 21st, 22d, and 23d.

THE WEST VIRGINIA STATE MEDICAL SOCIETY.—The Medical Society of the State of West Virginia will hold its sixteenth annual meeting at Grafton on Wednesday, May 16th.

THE PENNSYLVANIA STATE MEDICAL SOCIETY.—The thirty-fourth annual meeting of the Medical Society of the State of Pennsylvania will be held at Norristown on Wednesday, Thursday, and Friday, May 9th, 10th, and 11th.

THE CHAIR OF PHYSIOLOGY AT THE UNIVERSITY MEDICAL COLLEGE.—We understand that Dr. Louis A. Stimson has been appointed to the chair of physiology in the Medical Department of the University of the City of New York, to succeed Dr. J. W. S. Arnold, who is made professor emeritus.

THE ALUMNI ASSOCIATION OF BELLEVUE HOSPITAL MEDICAL COLLEGE.—At the annual meeting held April 21st, the following gentlemen were elected officers: President, F. A. Castle (re-elected); First Vice-President, V. P. Gibney; Second Vice President, W. T. Alexander; Recording Secretary, R. Van Santvoord; Corresponding Secretary, R. Newman; Treasurer, W. H. Katzenbach; Historian, F. A. Castle. Managers, to serve until 1884: J. D. Bryant, F. A. Castle, W. A. Ewing, F. E. Hyde, G. R. Kent, W. T. Lusk, R. Newman, J. R. Taylor, C. Terribery, R. M. Wyckoff. To serve until 1885: E. S. Bunker, L. J. Godon, G. Griswold, E. M. Lyon, E. A. Maxwell, J. B. Messimer, J. J. Van Voorst, Jr., W. R. Varick, D. L. Wallace, T. Wilde. To serve until 1886: G. W. Bull, T. H. Burchard, V. P. Gibney, E. C. Harwood, A. M. Jacobus, C. A. Leale, A. V. B. Lockrow, L. H. Sayre, A. A. Smith, L. M. Yale. To serve until 1887: W. T. Alexander, F. H. Bosworth, F. S. Dennis, W. H. Katzenbach, S. N. Leo, J. P. Munn, L. Putzel, G. H. Swezey, R. Van Santvoord, W. G. Wylie.

HOSPITAL STEWARDS IN THE ARMY.—The surgeon-general of the army announces that hospital stewards of the first class are appointed only from among the enlisted men who, as hospital stewards of the subordinate classes, have proved themselves worthy of advancement. At present there is but one vacancy.

THE MASSACHUSETTS STATE BOARD OF HEALTH AND THE TEWKSBURY ALMSHOUSE.—The Governor of Massachusetts having requested the State Board of Health to appoint an officer to take charge of the Tewksbury Almshouse for the time being, it is reported that the board declines to do so, and has sought legal advice as to its discretionary power in the matter.

THE COUNTY MEDICAL SOCIETY AND THE UNITED STATES MEDICAL COLLEGE.—We are glad to see that the danger of legislative action being carried to resuscitate the United States Medical College, to which we lately called attention, is appreciated by the Medical Society of the County of New York. At the meeting held last Monday evening nearly if not quite all the members present signed a petition praying the Senate to kill the Assembly bill devised to compass the base purpose of setting the so-called college on its feet again.

THE BOSTON WATER BOARD.—Last week we announced the nomination of Dr. John G. Blake as a Water Commissioner. We are happy to be able to announce that this admirable appointment has been confirmed by the Board of Aldermen.

A NEW ANTIPYRETIC: KAIRINE.—At a recent meeting of the *Société Médicale des Hôpitaux*, of Paris, M. Hallopeau announced that kairine exerted a remarkable antithermic action in most pyrexial affections. Given in doses of half a gramme (about seven grains and a half) every two hours, it causes free sweating and a notable lowering of temperature at the end of two or three days. The action may be kept up for a long time without danger of poisoning. [It may be remarked that two or three days is a long time to wait for the action of an antipyretic.]

THE COST OF MEDICAL CHARITY IN EUROPE.—According to the "Union médicale," the annual public expenditure for medical assistance is 7'61 francs in Vienna, 7'28 francs in Stockholm, 5'86 francs in Christiania, 5'80 francs in Prague, 5'72 francs in Berlin, 15 francs in Paris, and 11'24 francs in London.

DEATH OF DR. EDWARD B. TURNIPSEED.—Dr. Edward Berrian Turnipseed, of Columbia, S. C., died on the 18th inst., at the age of fifty-four. Dr. Turnipseed was widely known as an occasional contributor to the medical journals. In the early part of his career he was a mili-

tary surgeon, serving as a surgeon-major in the Russian army during the Crimean War.

DEATH OF DR. DAVID CUMMINS, OF LOUISVILLE.—The "Louisville Medical News," speaking of the late Dr. David Cummins, who died on the 14th inst., says: "Dr. Cummins had just passed his fifty-eighth birthday. For more than three months he had occasionally complained of vertigo with more or less headache. Two weeks since, a violent pain in the right frontal region forced him to bed, and from this time he was never thoroughly conscious. Dr. Cummins was a successful practitioner in the departments of surgery and obstetrics as well as in general practice. He was a man of strong practical common sense, of sunny temper, and attractive manners. He possessed the regard and respect of his brethren and the devoted love and admiration of a vast *clientèle*. His practice was probably the most lucrative in the city, and by it he had amassed a large fortune. He was 'a good man, skilled in healing.' The death of no other man is so great a calamity to a community as is that of a great physician. Such a loss Louisville sustains in the death of Dr. Cummins."

DEATH OF SURGEON-GENERAL JAMES C. PALMER.—Surgeon-General James C. Palmer, United States Navy (retired list), died in Washington, on the morning of the 24th inst., at the age of seventy-two. He was a native of Maryland, and was appointed Assistant Surgeon in the navy March 26, 1834, being assigned to the frigate *Brandywine*, of the Pacific squadron. In 1836 he sailed around the world in the *Vincennes*, and in 1838 accompanied an exploring expedition. Dr. Palmer was commissioned as Surgeon October 27, 1841, and attached to the sloop *St. Mary's*, home squadron, from 1844 to 1846, and in 1850 was assigned to the *Vandalia*, Pacific squadron, where he served until 1853, when he was attached to the receiving-ship *Baltimore*. In 1857 he joined the cable expedition in the frigate *Niagara*, and in 1858 the sloop *Macedonian*, of the Mediterranean squadron. In 1861 he was ordered to the Naval Academy, and, after a short service there, was in 1863 made fleet surgeon of the West Gulf squadron, with headquarters on the flagship *Hartford*, being on that ship at the time of Admiral Farragut's brilliant achievement in passing Forts Morgan and Gaines at the entrance to Mobile Bay, August 5, 1864. He was ordered to the Naval Hospital, New York, in 1866, and in 1869 was placed on special duty at Newport, R. I. In 1872 Surgeon Palmer was appointed chief of the Bureau of Medicine and Surgery, and retired from active service June 29, 1873. He was a man of high culture and much literary attainment, singular purity and refinement of character, devoted to his friends, and faithful to every obligation of duty during nearly half a century spent in the public service.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from April 14, 1883, to April 21, 1883.*—WOLVERTON, WILLIAM D., Major and Surgeon. Granted leave of absence for four months on surgeon's certificate of disability. Par. 7, S. O. 85, A. G. O., April 13, 1883. —SHUFELDT, ROBERT W., Captain and Assistant Surgeon. To report in person to the president of the Army Medical Examining Board in session in New York city for examination for promotion, on completion of which will return to proper station. Par. 10, S. O. 87, A. G. O., April 16, 1883.

NAVAL INTELLIGENCE.—Surgeon H. J. Babin has been ordered to duty at the Marine Rendezvous, New York. —Passed Assistant Surgeon William G. G. Willson has been ordered to the training ship *Minnesota*. —Surgeon Dwight Dickinson has been ordered to the Naval Hospital at Mare Island. —Surgeon George A. Bright has been detached from the Naval Hospital at Mare Island, and placed on waiting orders. —Surgeon Henry Stewart has been detached from the Michigan, and ordered to report for medical survey. —Passed Assistant Surgeon George H. H. Harman has been detached from the training ship *Minnesota*, and ordered to the Michigan. —For the foregoing items we are indebted to the "Army and Navy Journal."

SOCIETY MEETINGS FOR THE COMING WEEK.—*Tuesday, May 1st*: Medical Society of Hudson County, New Jersey (annual meeting); Neurological Society; Obstetrical Society (private). *Wednesday, May 2d*: Medical Society of the County of Richmond.

Lectures and Addresses.

LECTURES ON HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., ETC.

LECTURE IV.

Automatism in Intellectual Action.—Formation of Perceptive Judgment, as a General Resultant of Previous Experience. "Common Sense" derived from like Integration of Experiences. Source of our Belief in the Reality of the External World, and in the Distinction between our Sleeping and Waking States. Ideational Automatism. Trains of Thought. Influence of Intoxicants and Morbid Poisons.

If I have been successful in the last two lectures, I have led you up to this position—that the bodily movements in which our animal life essentially consists are all really automatic, either primarily or secondarily, even those which we call voluntary being the result of the training that we have given to our automatism, and of the substitution of impulses given by our own minds through the instrumentality of the cerebrum for those that originate in some external stimulation. Of this we have an apposite illustration in an action to which I called your attention in the first of these lectures—that of coughing. For, on the one hand, a cough (which involves the combination of a great number of separate muscular actions) may be involuntarily excited by irritation of the surface of the air-passages, the effect of which is propagated to the respiratory center, whence it is reflected to the muscles; and the provocation may be so strong that we can not resist it by the strongest voluntary effort. On the other hand, we can cough voluntarily; and we do this, not by a determinate or intentional calling into action of the several muscles which must combine to execute our mandate, but by simply issuing the direction to our automaton, on which it acts forthwith.

That you may more readily apprehend the application of this principle to voluntary motion generally, I shall ask you to follow me in a little experiment which every one of you can readily perform either upon himself or herself, or upon another person. It occurred to me while I was lecturing to a medical class, some thirty years ago, upon this subject. I wanted to impress upon the minds of my pupils what I shall endeavor to make clear to yours—that when we *will* to do an action we will the *result*, but not the particular combination of muscles that shall be called into action to produce that result. For I hold that we have no power to select any muscle or muscles in the body and say they shall do this or that. We have to will the result, and the body does it for us when we have trained it to do so, or, in some instances, without any training at all. This last is the case with the movements of our eyes, which, without any training, but in virtue of the original endowments of the visual nerve-centers, direct the axes of both toward the same object, although, when this direction involves any *lateral* movement, *opposite* muscles are called into action on

the two sides. I suppose you are all aware that each eye is chiefly moved by four muscles—one above and one below, one on the inner and one on the outer side. These are called the *recti* or straight muscles. Besides these, each eye has two *oblique* muscles, to the functions of which I shall presently direct your attention. Now, you can easily understand that the recti muscles, either singly or in combination, can roll the ball of the eye in any direction. Contraction of the superior rectus (the straight muscle above the eyeball) shall roll it upward, while that of the inferior rectus rolls it downward; the external rectus rolls the ball outward, while the internal rectus rolls it inward. Now, when we raise both our eyes together to look at an object above us, we employ the corresponding muscles; as we do, also, when we lower both our eyes together so as to look downward. But when we direct the axes of our eyes toward an object on either side, one eye is rolled outward by the external rectus, while the other eye is rolled inward by the internal rectus; we then combine two muscular actions harmonically to produce the result, although the actions themselves are contrary. When, again, we determinately fix our gaze upon a near object directly in front of the nose, the internal recti of the two eyes act together, so as to draw the pupils toward each other; and this convergence becomes very sensible to another person when we gradually bring the object so near the eyes as to produce a feeling of tension in the muscles which, when put too much on the strain by the close approximation of the object, cease to maintain the convergence. We do all this without any thought or intention; and just as well without the least idea of the combination we are making as we can with the most accurate knowledge of the apparatus we are employing. We *will* to fix our gaze on one spot or another; and our automaton calls the suitable muscles into simultaneous action. Thus, I will to fix my eyes upon that clock, and I will at the same time to rotate my head horizontally to one side or to the other; and those who are near enough to me will see that my eyes will roll in their orbits from side to side in the contrary direction. Now, I am not in the least degree conscious of that movement of my eyes; it is purely automatic. The eyes roll because I have determined that, while moving my head to one side or the other, I will look fixedly at the clock, which fixedness involves the direction of the axes of the eyes so as to meet in it. In the same manner, if, while still fixing my gaze on the clock, I move my head either upward or downward, you will see that my eyes will move in the contrary direction; and this, as in the previous case, without any consciousness of muscular effort on my own part, the action being guided, not (as in most other cases) by the muscular, but by the visual sense.

There is another movement of the eyeballs which is extremely curious, and which was first elucidated by my distinguished friend, Professor Helmholtz, of Berlin. The action of what are termed the *oblique* muscles had long been a puzzle to physiologists; for it was clear that the four *recti* were sufficient to roll the eyes not only upward and downward, inward and outward, but in any direction inter-

mediate between these. Careful study of the subject, however, had rendered it probable that they give the eyeball a rotation around its antero-posterior axis, the pupil remaining fixed; but no one could assign any purpose for this rotation until Professor Helmholtz, in the "Croonian Lecture on Muscular Motion," delivered before the Royal Society in 1864, not only established the fact by a new and admirable mode of demonstration, but gave the *rationale* of it. When I rotate my head horizontally, while looking at that clock, the place of its image on the retina would be changed so as to give the object an apparent motion, if it were not for the converse automatic movement of my eyes, which keeps the image on the same spot of its surface. And so, when I *incline* my head to one side or the other while still looking fixedly at the clock, the retinal image would be (as it were) twisted round in the opposite direction, giving an apparent rotation to the object—if it were not that the eyeballs are automatically turned round their antero-posterior axis, by the oblique muscles, in the contrary direction, so that every portion of the picture continues to hold its original position on the retina.

Here, then, is a clear case of the production of muscular actions, of which we are altogether unconscious, by willing the result which those muscles automatically execute. And I hold that the same is true of all so-called "voluntary" motions. None but those involving the very simplest combinations of muscular action can be executed without training of some kind; and it is only where the action of but one muscle is required to produce the result (as in the opening or closing of the eyelids) that we can single out any muscle and throw it into separate contraction.* But we can choose among all the actions which we have trained our automaton to execute, can say to it, "Do this," and the obedient machine does it without thought or consciousness of effort. Thus, when I was coming out this evening, I (mentally) said to my automaton, "Walk to the lecture-hall," and he brought me here while I was thinking all the time of the lecture I was about to give.†

I shall give you yet another illustration from an automatism we all acquire—that, namely, which takes place in the act of writing. It has probably happened to most of you all, as it often happens to myself, to misspell a word, or to write a wrong word. This generally results from the automatic combination of a coming word, or of some part of it, with what I had previously charged it to put on paper. While my hand is tracing the characters, my consciousness has been preparing fresh matters for expression; and the automatism has laid hold of this, as it were, a little too

soon, so as to introduce a letter or letters, or perhaps a syllable, or perhaps a whole word, into the matter which I had already directed it to express. This I believe to be a very common experience among men who use the pen much; and I may give you the parallel to it in a case of verbal dictation to an amanuensis.

It is recorded by John Bannatyne, who sometimes acted as the amanuensis of Sir Walter Scott, that when Scott was dictating to him the stories of his novels he would sometimes interject a word that was obviously wrong, having no connection with what preceded it. Bannatyne came to perceive, however, that this wrong word was almost always one that would have its proper place a line or two onward; so that Walter Scott must have already prepared it in his mind for dictation, and let his automaton get hold of it too early.

This automatism of our bodily organization, and the power we possess of utilizing this to our own purposes, constitutes the first general conception that I would have you shape out of the material I have placed before you in the preceding lectures. And I trust that I have further satisfied you that the secondary or acquired automatism, when a combination or succession of movements has been so frequently practiced as to become habitual, is so embodied in our organization that such successions may go on by themselves when once they have been put in train. There can be no reasonable doubt that the nervous apparatus *grows* to the mode in which it is habitually called into activity; and that thus a new mechanism gradually constructs itself, which enables actions that once required the closest attention for their due guidance to be performed automatically without any attention whatever. And I may add that I think there is much evidence of the hereditary transmission of such acquired organization, especially if it has been shaped in early life.

You are all aware of the influence of *age* in the formation of habits, and know how tenaciously the habits formed in early life cling to us. The physiologist has no difficulty in explaining this, in regard either to bodily or to mental habits. For it is during the early period of life that the body, while undergoing its development, has to create a great deal of new structure; and the habits, whether bodily or mental, that we then form, govern the building up of that structure. It is not until adult age that this building process is completed; and the organism then tends to maintain itself throughout life according to the plan with which it has been thus brought into conformity. Now, if we attempt to modify that plan afterward, by the subsequent formation of new habits, we do not succeed in impressing those habits upon the organization nearly as thoroughly as we do during the growing state of the body. This is a simple physiological fact; and it has a most important bearing upon the transitory character of later acquirements, that are not constantly kept up by practice, as compared with those of our earlier life, which keep themselves up without effort. Thus, even the most accomplished musical performers do not venture long to discontinue the "practice" of their vocal or instrumental parts, however familiar they may be with them mentally. The

* I have been asked how I reconcile this principle with the fact that almost any man may put his *biceps* into such strong contraction as to make it rise as a hard lump on the middle-front of his arm. Nothing, in reality, could be a better illustration of the doctrine. For no one can thus raise his biceps into a lump without (unknowingly) throwing the *triceps extensor* of the back of his arm into simultaneous contraction; since, without its antagonism, the contraction of the *biceps* would bend the forearm on the arm.

† In the classical "Voyage autour de ma chambre" of Count Xavier de Maistre, you will find this dual nature of man, as consisting of *âme* and *bête*, charmingly worked out by a deep thinker and accomplished writer.

greatest pianists will work most carefully upon any pieces that they are about to play in public; perhaps sitting up half the previous night in mastering the execution of particular passages, in order to train their muscles to express the ideal which their minds conceive. And I happen to know, through a friend—next door to whom Madame Patti lived during one of her opera seasons in London—that every morning her music-master came to her, keeping her for two or three hours in the practice of scales and shakes, and training her in the particular songs she was about to sing. Now, this will show you how quickly the automatism acquired in adult age fades out, as it were, if the training by which it was perfected is not persevered in, while, on the other hand, those things that we learn in our growing period become, as it were, part of our constitution. Thus, although the act of walking is in itself as difficult as any of these musical performances, we have never any trouble or difficulty in performing it, even after long disuse, except from bodily infirmity, or, as I pointed out in the last lecture, from the disturbing influence of our emotions—as when we have to walk across a narrow plank raised far above the ground, or with a rush of water beneath it.

The close correspondence that every one must recognize between habits of body and habits of mind makes it natural to pass from this subject to that which is to occupy us during the remainder of the course—the automatism of our mental life. And the first point I would press on your attention is, that during the whole waking existence our minds are in a state of constant successional change. The late Professor Clifford once began a lecture at the Royal Institution by saying: "If any one were to ask us what we had been doing during the day, it would not be an incorrect answer to say that we had been constantly changing our minds." That was only his humorous way of expressing, by a new turn given to a familiar phrase, what every metaphysician knows to be true—that our whole mental life is a succession of states of consciousness. I shall confine myself this evening to those purely *intellectual* states into which feelings and emotions do not enter—the reception of sensations unaccompanied with feelings of pleasure or pain, the formation of perceptive judgments, and the succession of ideas which constitutes thought.

On so large a subject as this it is, of course, impossible for me to dilate with any fullness; and I deem it better to limit myself to a small number of points which admit of ready illustration than to attempt to cover a wider space by more systematic exposition. And the first of these points has reference to the automatism of sensation itself.

I have already spoken of the mode in which our consciousness becomes affected through the nervous system. When I prick my finger, or some one else pricks it for me, I feel a pain (as we commonly say) in my finger. But I do not really feel the pain in my finger. The feeling of pain is a subjective state, a mental condition, brought about by that wonderful translation, of which I spoke in my first lecture, of a *neurosis* into a *psychosis*. That translation takes place in a certain part of my brain—the ganglionic center of the nerve proceeding to it from my finger. But, by what Professor Huxley has appropriately called an

"extradition" of my consciousness, I locate that pain in the point in which the pin was run into my finger. Now, this is a purely automatic action, of which we can give no other account than that it is a part of our constitution, which (as we have every reason to believe) we share with the lower animals. Various attempts have been made to explain it; but all we can say is, that it has reference generally, though not uniformly, to the particular nerve-track along which the impression has been conveyed. For we find the mental reference made when there is no corporeity answering to it. Thus, it is a very well known fact that persons who have suffered the amputation of a limb, for some time—it may be for a long time afterward—feel pains which they refer to the lost member, and generally to the extremities of it. Here the physical condition that excites the neurosis probably has its seat in the cut end of the nerve which has been inclosed in the skin that covers the stump of the amputated limb; for there is no doubt that many of the most severe pains of this kind have originated from some special morbid change at the extremities of those nerves.

The reference of these pains to a non-existent limb is thus an automatic mental act—whether a part of our original constitution, or one acquired by an early generalization from experience, it may be difficult to say.

We seem justified in taking the same view of those other cases of what are called "radiating sensations," in which the physical change that originates them has its seat either in the nervous centers, or in some part of the nerve-track leading to them, and which we refer to the extremities of the nerves through which they have been brought to the centers. We may produce an impression that shall give flashes of light, for instance, by galvanizing the optic nerve in its course, while no light falls on the retina. There is an old experiment which I remember making when a boy—putting a half-penny between the upper lip and the teeth as far up as it will go, and a bit of zinc on the tongue, and then making the one touch the other, the eyes being closed; a flash of light is seen every time the contact is repeated. So, again, by galvanizing the auditory nerve we may call forth sensations of sound. And the "fornication," or the pricking sensations (pins and needles), which we experience on the renewal of the circulation in a limb after it has remained "asleep" for a time in consequence of defective circulation through it, are due to such physical excitation of the nerve-trunks as serves to call forth in their ganglionic center the changes of which those sensations are the "symbols in consciousness," our automatism referring those sensations to the locality from which the impressions usually arise which excite that condition of the nerve-center. And another case of a like kind is afforded by the "ringing in the ears," when this is produced by mechanical pressure upon the auditory nerve distributed within the labyrinth, or by the pulsations of the carotid artery against its trunk. Disease of the nerve-centers is another very frequent cause of these "subjective sensations"; our reference of which to the organs wherein such sensations ordinarily originate is an act of mental automatism which we are incapable of modifying by any act of our will. So, we find

quently experience sensations which are called forth by purely mental antecedents, in which we can trace a secondary automatism that has grown up through acquired experience.

It may have happened to many of you to feel a degree of seasickness, or, at any rate, of the discomfort in which that state ordinarily commences, from the mere contemplation of an agitated sea, especially in view of a ship tossing about in it. And I remember very well that when, at one of our semi-scientific or popular exhibitions in London, there was a small model of a ship, which floated (as it were) upon a sea of gold-beater's skin, and was made, by a concealed combination of levers, to go through a series of movements remarkably resembling the pitching and rolling of a ship at sea, with an occasional sinking down into the trough of a wave, many persons said that they could not continue to look at it without sensations which made it desirable for them to turn away. I was once told of a lady who accompanied a friend to see her off by steamer, I think across the British Channel, and on whom the sight of the rough sea and of the heaving of the vessel at the pier was sufficient to excite real and complete seasickness. Clearly it was the mental state, in these cases, that called up a physical condition of the central organs, so far corresponding to that which the actual experience would have done as not only to produce the sensation but the reflex act prompted by it. It was not the mere sight, but the associations connected with the sight, that brought about that feeling. There is an old story told of himself by a very able physician of his day, Van Swieten, which is an excellent illustration of this tendency to the reproduction of a former physical state by a strong mental impression. He says that he once happened to pass a place where there was a body of a dog in a state of such loathsome decomposition as to produce upon him the physical result to which I have just now alluded. Some years afterward, in passing the same spot, the remembrance of what he then saw and smelt came upon him with such vividness as to reproduce the same result.

Now, I wish you to take in what I regard as the physiological mechanism of these occurrences, because I regard them as types of a great number of cases which are elucidated by the same interpretation. You will remember that, according to the view I have presented to you of the relation between the cerebrum and the sensorial centers at its base, it is through the latter that those changes are excited which first affect our consciousness, while it is only when the cerebrum is called into action that these changes are intellectually apprehended. Of what we term *perception*—the mental recognition of the objectivity of the source of the sensation, and the formation of a judgment as to its character—the cerebrum (we have every reason to believe) is the material instrument. The optic nerve, in the cases I have described, brings to the optic ganglion the physical impression that is converted into the elementary *psychosis*, the mere sensation; but that sensation does not originally give us any idea of the object of the sensation. The formation of that idea depends on the transmission of the effects of the neurosis to the cerebral hemispheres, the automatic working of whose mechanism, as I shall presently endeavor

to show you, translates that neurosis into the idea or intellectual concept of the object which produced the sensation. This psychosis, if transformed back into a neurosis, may act downward upon the sensorial apparatus, so as to produce therein a physical state identical with that which the impression of the actual object on the nerve of sense would excite in it.

Thus, in the case of Van Swieten, the impression originally produced on his sensorium by the sight and smell of the dead dog, reacting downward through the motor nerves to the muscles concerned in the act of vomiting, called forth that movement; but, at the same time, its transmission to the cerebrum left the impression which constituted the physical basis of the mental remembrance of the occurrence. Years afterward, this record was called into active operation by the mere sight of the place, reviving the recollection of the whole former experience. And the physical condition thus excited in the cerebrum by the remembrance of the object played downward so effectually on the sensori-motor apparatus as to produce a repetition of the act which had been consequent on the stimulation originally given by the impression made by the actual object upon the organs of sense.

I believe that a considerable number of what are called "spectral illusions" have exactly this character; and some of you may be interested in the view I take of what my friend, Mr. Francis Galton, has called "visualized numerals," upon which I know that some observations have been made by Professor Bowditch in this city. He has been kind enough to give me the particulars of a case that presented itself in his class, in which a very marked form of this visualized presentation of the numbers has occurred. Mr. F. Galton has found that there is one in about every twenty or thirty persons who, whenever he thinks of the succession of numerals, sees the figures visually projected before him in some definite arrangement; and in Professor Bowditch's pupil this arrangement varies from any recorded by Mr. F. Galton in the numerals not being seen in one plane, but in a figure of three dimensions. Sir John Herschel, I may mention, communicated to me many years ago a set of geometrical figures which he was accustomed, every now and then, to see projected upon any object which he was looking at, and asked my opinion about it. I told him that I thought there was no difficulty in understanding it upon this view: the visualized numerals in Mr. Francis Galton's case, and the mathematical figures in Sir John Herschel's, being formed, as it were automatically, by cerebral action, and their resultant neuroses being transmitted downward to the sensorium, so as there to mingle, as it were, with the sensory impressions derived through the eye, so that the one set would be combined with the other. The seat of the consciousness of the cerebral impressions being (on this view) the same as the seat of our ordinary visual consciousness, the physical impressions transmitted downward by the automatic action of the cerebrum through the converging fibers, which an old anatomist, Reil, sagaciously called "the nerves of the internal senses," would produce visual sensations as real as those ordinarily excited through the nerves of the external sense-organ. And it is, I think, by this in-

strumentality that many blind persons can call up visual pictures of objects they have once seen that are not less vivid than those originally excited by the actual sight of those objects.

We have a still more remarkable illustration of this automatic production of visual images in the phenomena of *delirium* produced by the circulation of poisoned blood in the brain. From the manner in which old visual impressions are reproduced in new combinations, and the intense vividness with which it is obvious to the bystander that these creations of his brain are *seen* by the patient, I can not doubt but that the same physical condition must exist in his sensorium as would be called up through his visual sense if the real objects were present; and, as all our information in regard to the *storage* of former impressions leads us to regard the cerebrum as the physiological seat of it, I think you will see how readily and simply all these phenomena find their expression in automatic cerebral action, translated into consciousness through the instrumentality of the *sensorium commune*.

(To be concluded.)

Original Communications.

REMARKS ON CASES OF KATATONIA.*

By WILLIAM A. HAMMOND, M. D.,

SURGEON-GENERAL, UNITED STATES ARMY (RETIRED LIST), PROFESSOR OF DISEASES OF THE MIND AND NERVOUS SYSTEM IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL, ETC.

By katatonia is to be understood a form of insanity first described by Kahlbaum† and characterized by alternate periods, supervening with more or less regularity, of acute mania, melancholia, and epileptoid and cataleptoid states, with delusions of an exalted character and a tendency to dramatism. The derivation of the word (*κατατονος, stretching down*) is taken by Kahlbaum to express the depressed mental and physical tension which is characteristic of the disease. From his monograph, from that of Dr. J. G. Kierman,‡ of Chicago, the only writer in the English language on the affection, and from the observation of cases occurring in my own practice, I shall take the description I am about to give.

Katatonia may, like other varieties of insanity, be preceded by prodromic symptoms. There are pains or other abnormal sensations in the head, vertigo, insomnia, irritability of temper. Again, it may begin with an epileptiform convulsion, or the condition of melancholia or exaltation may be the first noticeable symptom. Then the cycle begins: Cataleptoid phenomena accompany or follow the

melancholia, which is generally of the form described as melancholia with stupor, and a period of excitement supervenes, during which the patient has sensorial derangements in the way of illusions and hallucinations as well as delusions. Again, the melancholia appears, perhaps, in a modified form, with cataleptoid and waxy conditions of the muscles, and a disposition to talk in an exalted or dramatic manner. At times, during the course of the affection, there may be convulsions or involuntary muscular actions, such as rolling on the floor or bending of the body. Masturbation is a common accompaniment, and during the stage of excitement acts of violence may be committed.

The further description of the symptoms will be best given by the detailed account of the cases that have come under my observation:

A merchant engaged in the importation of Vienna goods consulted me March 11, 1880, or rather I was consulted in regard to him by his brother and one of his partners in business, and the patient, very much against his will, was brought to my consulting-room.

He entered the apartment with all the air of a prince, and sat down without deigning to address me. When I spoke to him he at first made no answer, but on my persistence with my questions of what his name was and where he lived, he looked at me for a moment in a supercilious way and finally said, "And the Lord spake unto Moses, saying." This he kept repeating, whether spoken to or not, during the whole of his visit, extending over an hour. Upon inquiry, I ascertained that without assignable cause he had, eight days previously, suddenly passed into a condition of melancholia with stupor, during which he was most of the time silent and in a state of almost complete immobility. It was also [noticed that, when anybody took hold of his hand, the member remained for several minutes in the position in which it was left. On one occasion his neck had continued twisted, with his face as far as it could be turned over his left shoulder, for over half an hour, and had then slowly returned to its natural position. On my taking hold of his arm and extending it at right angles with his body, and leaving it there, it remained outstretched for thirteen minutes, and then slowly descended to his side. All the time that I was making this and other examinations of his muscular system, he was saying in a loud voice, "And the Lord spake unto Moses, saying."

The pupils were equal, were largely dilated, and did not react well to light.

I requested him to follow me into another room, in order that I might make an ophthalmoscopic examination. He took no notice of what I said to him, and, when his friend and I raised him from his chair to lead him into the apartment, he made himself as rigid as a bar of iron, so that we had to carry him. Arrived there, he would not sit down, but stood as erect as a statue. On feeling his muscles, it was easy to perceive that all were in a state of extreme tension. It was impossible, I found, to make the examination I desired; so, after prescribing the bromide of sodium for him, in doses of twenty grains three times a day, I sent him away, with instructions to return in five days, and to continue the medicine till then.

* Read before the New York Neurological Society, March 6, 1883.

† "Klinische Abhandlungen über psychische Krankheiten," i. Heft "Die Katatonie," Berlin, 1874.

‡ "Katatonia," "Alienist and Neurologist," October, 1882, p. 553. This paper was originally read before the New York Neurological Society, May, 1877, and was published in the "American Journal of Insanity" for July, 1877.

On the 16th I saw him again. He was then in a state of high excitement. He entered the room without hesitation, and at once began an extemporary speech on the beauties of the solar system. Every sentence, however, he ended with the phrase, "And there shall be no night there." I wrote down from memory soon after his departure a portion of his address, as follows:

"And now, my friends, what is this solar system of which we have heard so much? And there shall be no night there. Is it composed of homogeneous matter throughout its whole extent, or are some parts of it different from others? And there shall be no night there. Is it to be supposed that the sun, a light-giving orb, is of the same physical structure as the moon, a light-reflecting orb? And there shall be no night there. Is the earth, a light-receiving orb, like the sun, a light-giving orb, and the moon a light-reflecting orb? And there shall be no night there"—and so on for half an hour.

Since his last visit he had had several spasmodic seizures without loss of consciousness, coming on before the cessation of the period of melancholia, which took place on the 14th of March. Since that time he had done very little else than to declaim from Shakespeare and other poets, and deliver extemporaneous addresses. He was disposed to be very quarrelsome, and had knocked the hat off a man's head on his way to my residence, because he thought the man had made a face at him as he passed. The convulsive seizures had consisted of movements of the head and of the muscles of the neck. The head, for half an hour or more, had on several occasions been kept in continued motion from side to side, while the face was undergoing contortions. One afternoon he had stood before an engraving of Washington and bowed for over an hour, and would have continued had he not been taken away by force.

On my asking him how he felt, he answered, "It's a wise child that knows its own father, but I feel quite well, I thank you." On my asking how he had slept the previous night, he replied, "It's a wise child that knows its own father, but I slept very well, I thank you." When I asked if he had any pain in his head, he said, "It's a wise child that knows its own father, but I have no pain in my head, I thank you." And so on, to every question I put to him.

Before he left, he began to speak in a staccato way: "I—think—I—shall—go—to—the—the—a—tre—to—night—to—see—Booth—in Ham—let."

I asked him why he spoke in that manner. He replied: "Be—cause—I choose—to do—as—I choose—to do—and that—is—why—I speak—as—I choose—to—speak."

"But," I said, "it is a silly way of talking."

"I—came—to you—for—med—i—cal—advice—and—not—for—a—les—son—in—el—o—cu—tion."

At this time there were the ophthalmoscopic appearances of cerebral congestion. The pupils were normal.

So far as I could ascertain, there had been no illusions or hallucinations, but there were delusions that he was to be made the director of the opera and manager of all the theatres, with a large salary from the State.

I directed the continuance of the bromide of sodium. On the 22d I saw him again. There was then a condition

of catalepsy, without marked melancholia. Though indisposed to talk, he would answer if the question were repeated. The arms, legs, and head were in a waxy state, and at times he would take dramatic attitudes and keep them for several minutes. He stood in my consulting-room for seven minutes as "Ajax defying the lightning," and for the like time as the "Apollo Belvedere." "The dying Gladiator" he could only maintain for a few minutes.

At the time there was no mental aberration of any kind, but there was a slight degree of exhilaration present which was not natural to him, and a slight disposition toward dramatism. This, however, did not extend to speech, but only to the attitudes which he would assume without prompting.

Under the continued use of the bromide, this state passed away in a few days, and there were no further manifestations of the disorder.

The next case that came to my notice was that of a young German, living in St. Mark's Place in this city, whom I saw in consultation with the younger Dr. Garrish. In this instance, the cataleptoid state and the tendency to utter high-flown language, and to assume histrionic attitudes, were strikingly exhibited. At the period of my examination the mental condition was that of excitement. The patient was talking volubly nearly all the time, walking the floor, gesticulating, grimacing, and occasionally speaking in alliterative verse. He had hallucinations of hearing, and would often stop and listen for an instant with a rapt expression of countenance. Then he would exclaim in pompous tones, "My lord, it shall be done!" This he repeated many times. He had passed through a stage of melancholy before I saw him. This had lasted a week or more, and during its continuance the patient mostly sat motionless in a chair, mute to all questions, and never taking the initiative in talking. Frequently, however, when spoken to, though he would not answer, tears would flow in profusion, and he would groan aloud. He afterward said that he had not spoken, because he had the idea that it had been decreed that, if he uttered a single word, his mother would at once die. I did not see this patient again, but was informed that he recovered under the bromide treatment advised. The pupils were contracted, and the optic disc and fundus of the eye congested.

The third case was that of a physician from a Southern city, who was brought to me by his friends, August 31, 1882. He was then in the stage of melancholia with stupor, attended with cataleptoid symptoms. He would not speak, but sat as long as allowed, motionless, with his eyes cast on the ground. If physical efforts were made to move him, his whole muscular system was thrown into a state of extreme tension. If the attempt were made to raise his arm from his side, for instance, the limb became rigid, and it was almost impossible to move it; at the same time there was no sign of any voluntary effort at resistance on his part. He sat as composedly as before on his chair, without a change of countenance, though the muscular strength brought to bear by him was certainly very great.

When I requested him to walk into an adjoining room, in order that I might make an ophthalmoscopic examina-

tion, he sat without moving a muscle. It was necessary to carry him, but, as soon as touched for that purpose, his body became perfectly rigid, and he could not even be made to sit down. He stood as erect as a statue. He appeared to be in a condition not unlike that of a person suffering from tetanus, in whom the slightest impression made upon the skin is sufficient to induce a spasm.

Previous to my seeing this patient, he had had repeated paroxysms of excitement, alternating with periods of melancholia, with stupor and cataleptoid phenomena.

After leaving New York, he improved to some extent, and would have improved still more, could he have been induced to take the mixture of bromide of sodium and fluid extract of ergot prescribed for him.

The only other case of katatonia that has come under my observation is that of a Swede, a man of about thirty years of age, who came to my clinique at the New York Post-Graduate Medical School February 15, 1883, and who formed the subject of a clinical lecture delivered to the class of medical practitioners in attendance. Twelve years previously, the man, while working in a stone-quarry, had a piece of timber fall upon his head. He was stunned for a few minutes, but the blow was not a serious one, and he recovered; subsequently, however, he had some head trouble, and did not speak for several weeks. All morbid symptoms disappeared, and he remained well till about twenty days before I saw him, when he became excited, thought people were going to kill him, that he had committed some crime, etc. This state only lasted a few days, when it was succeeded by a period of melancholy with stupor, during which he was mute, and sat nearly all day in one position. If his baby were put into his arms, he would hold it

amination, I soon discovered the cataleptoid phenomena and the rigid state of his muscular system generally. Before the class, I stretched out one of his arms, and he kept it in a perfectly horizontal position for over ten minutes, when his brother, fearing he might be injured, put it down. Again, on trying to raise his arm, it was held so strongly against his side that it was impossible to move it. No answers could be obtained from him. He sat bolt upright, staring at vacancy without the least expression, unless it were one of slight astonishment, on his face. The engraving, made from a photograph taken that afternoon, shows the expression of his countenance admirably—an expression which is perfectly characteristic. This attack was supposed by his father to be due to grief caused by the death of one of his children about a month before. I prescribed the bromide of sodium in doses of thirty grains three times a day, and directed him to return in a week for further observation. On his return at the time fixed upon, the cataleptoid phenomena had entirely disappeared, but there was still a tendency to dramatism. He came again on the 1st of March, and was discharged cured.

Many cases of unrecognized katatonia are to be found reported in writings on psychological medicine. One of the earliest is the following:*

James W. L., aged twenty-nine, was admitted into the hospital May 10, 1821. This young man had been a patient in the hospital before, and had remained for twelve months, when he was placed in the incurable list; but, having got much better, and continuing to improve for some time, six months' leave of absence was granted him, at the end of which time he came back completely well, and was discharged cured.

The character and symptoms of this patient's disorder, it is stated, were extremely curious. When the paroxysm came on, however he happened to be situated, his whole form from head to foot became stiff, as if all his joints and muscles were ossified. His eyes, though staring open, became fixed, and he foamed at the mouth. If sitting or walking, when his fit came on, he would instantly fall to the ground, completely extended at full length on his back with the same symptoms of rigid stiffness and insensibility; his eyes, opened and inclined upward, were insensible to the touch of a hand passed over them, which did not produce the slightest wink. No symptom of animation remained, with the exception of breathing, but this so faint as to be scarcely perceptible. His condition, in all other respects, resembled death, and in this state he would sometimes continue for one, two, three, and even four days, without any apparent change. He could not be induced on these occasions to eat or take any kind of sustenance, except under the direction of medical gentlemen, when rich broths were administered by injection. During the fits his whole person was literally as stiff as a plank, and he might have been raised to a vertical posture and carried from place to place like a ladder without the least appearance of flexibility. Toward the termination of these paroxysms, when a hand was passed over the eyeballs, they would sometimes move, which was a prognostic of his recovery.

for hours without moving his hands or otherwise changing his position. He never asked for food or appeared to care about eating. If his meals were brought to him, cut up, and put to his lips, he would sometimes open his mouth and eat; again, he would refuse. In my preliminary ex-

* "Sketches in Bedlam," etc., London, 1824, p. 155.

ery. On being roused from his stupor, he recollected nothing of what had passed, but he would speak of dreams, visions, heaven, hell, and the strange things he had seen. After these fits he always appeared weak and dejected.

Other cases of a similar character have been reported by Cullere,* Lagardelle,† and others, but without differentiating the affection now under notice, and without reference to Kahlbaum's monograph. The disease is more common in men than in women. Of twenty-six cases reported by Kahlbaum, twenty were in males. All of Kiernan's cases were in males, but this is explained by the fact that the asylum of which he was one of the medical officers had only male patients. All my cases were also in males.

Katatonía is of rather favorable prognosis. It appears in the first stages, at least, to be a raw motor affection characterized by a paralysis of the vascular coats and by consequent cerebral hyperæmia. All my cases, except one, yielded readily to the bromide of sodium; that patient was not under my immediate care, and did not get the medicine prescribed.

THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.

BY HENRY G. PIFFARD, M.D.

Third Article.

HAVING considered briefly, but we believe accurately, the medico-political and medico-educational status of the profession in this State, we will now take up the question of its medico-ethical position and requirements.

As already noted, the earliest attempt at ethical regulation in this State was the adoption of the System of Ethics of the Medical Society of the State of New York in the year 1823, long before any other State had thought it worth while to move in the matter. This code remained in force until 1880. About the year 1850 the "Code" of the American Medical Association was also adopted by the State society, but without the repeal of the older code. The profession of the State were, therefore, under the guidance and governance of two distinct codes, the respective provisions of which were not altogether in harmony. Thirty-five years ago there were those who preferred the old State "System" to the "Code" of the American Medical Association; but, as by the adoption of the American Medical Association code there was a prospect of national unity on the matter, they yielded their preferences, and consented to be bound by both, thus accepting a measure of ethical responsibility in excess of that borne by the profession in any other State in the Union. At this time there was no other organized section of the profession to question the propriety of this code, or to propose the adoption of another. A few years later the homœopaths became organized, and acquired chartered privileges. They were, as already stated, an outcrop-

ping from the general profession, and thought best to follow its example and adopt a code. This code was an almost exact transcript of the American code, with the exception of the paragraph relating to the question of consultations. On this point they differed from the older code as follows:

"A complete medical education, of which the diploma of a medical college is the formal voucher, furnishes the only presumptive evidence of professional acquirements and abilities. But the annals of the profession contain the names of some who, not having the advantages of a complete medical education, became, nevertheless, through their own exertions and abilities, brilliant scholars and successful practitioners. A practitioner, therefore, whatever his credentials may be, who enjoys a good moral and professional standing in the community, should not be excluded from fellowship, nor his aid rejected, when it is desired by the patient in consultation. No difference in views on subjects of medical principles or practice should be allowed to influence a physician against consenting to a consultation with a fellow-practitioner. The very object of a consultation is to bring together those who may, perhaps, differ in their views of the disease and its appropriate treatment, in the hope that, from a comparison of different views, may be derived a just estimate of the disease and a successful course of treatment.

"No test of orthodoxy should be applied to limit the freedom of consultations. Medicine is a progressive science. Its history shows that what is heresy in one century may, and probably will be, orthodoxy in the next. No greater misfortune can befall the medical profession than the action of an influential association or academy establishing a creed or standard of orthodoxy or regularity. It will be fatal to freedom and progress in opinion and practice. On the other hand, nothing will so stimulate the healthy growth of the profession, both in scientific strength and in the estimation of the public, as the universal and sincere adoption of a platform which shall recognize and guarantee:

"1. A truly fraternal good-will and fellowship among all who devote themselves to the care of the sick.

"2. A thorough and complete knowledge, however obtained, of all the direct and collateral branches of medical science, as it exists in all sects and schools of medicine—as the essential qualifications of a physician.

"3. Perfect freedom of opinion and practice, as the prerogative of the practitioner, who is the sole judge of what is the best mode of treatment in each case of sickness intrusted to his care."

The additional sections of the homœopathic code so closely resemble those of the American code that they need not be quoted. They recognize the impropriety of advertising, of patenting surgical instruments, of practicing with nostrums, keeping secret the nature and composition of medicines used, etc.

A few years later, when the eclectics became organized, they also adopted a code—one that was likewise based on the American code, and differing from it mainly by reversing the intent of many of the most important sections of the older code as follows:

* "Observation de catalepsie chez un hypocondriaque persécuté," *Ann. méd.-psy.*, mars, 1877, p. 177.

† "Catalepsie consécutive à une manie aiguë," *Ann. méd.-psy.*, janvier, 1878, p. 38.

"ARTICLE III (*Eclectic Code*).

"Medical men have an undoubted right to bring themselves and their claims before the public by every fair and honorable means, as much as any other class of men. They may enter into general or special practice as they may consider best adapted to their interests or to their peculiar views; they may introduce themselves to the notice of the public by printed cards or other publications, by public or private lectures, or by the publication of certificates of cures actually performed. The presence of laymen at operations is by no means objectionable if both patient and operator shall consent, as it tends to make the skill and ability of the operator better known in the community, etc.

"ARTICLE V.

"A medical man having invented any surgical instrument, or discovered any new or valuable medicine, it becomes his capital, and it is not unprofessional for him to obtain a patent for the same. . . . A physician may employ, in his own practice, a medicine or compound known only to himself; it is his capital, and there is no authority in the land which can compel him to divide that capital among others by disclosing his remedy, save his own benevolence and philanthropy," etc.

Such is the "Code" of a body of men who would never have received governmental recognition if the educated members of the profession had not been engaging in a bitter internecine warfare.

This was the status of nominal ethics until within a recent period. The regular profession and the two sectarian bodies each had its code of ethics, differing from the others in the manner that we have seen. While the American code held sway over the great mass of the profession, sectarianism was increasing in power and influence. An evil which at its birth could have been easily controlled by wise measures was, on the other hand, injudiciously stimulated to an abnormal growth. For many years the American code had, in great measure, lost its vitality, and its edicts were not respected. One form of impropriety after another came to the surface, which it appeared unable to rectify or control. Eminent members of the profession began to violate not only its spirit, but its letter, and the corporate bodies of which they were members appeared unwilling or unable to subject them to discipline. About fifteen years ago the New York Academy of Medicine did discipline one of its members for consulting with a homœopath. Their experience on that occasion led them, quite wisely, to refrain from a repetition of the experiment. A few more such attempts would undoubtedly have led to the disruption of the Academy, and, in all probability, to a forfeiture of its corporate privileges. The suspension of the late Dr. Gardner from his rights as a Fellow of the Academy undoubtedly acted as a partial restraint on the other members of that body, and more especially on those who were comparatively young in the profession, or without sufficient influence to shield them from prosecution. As a matter of fact, two Fellows of the Academy permitted it to be publicly understood that they consulted with homœopaths, and would continue to do so as often as they

pleased. Despite this fact, these members have never been brought to the bar of the Academy for discipline.

In 1865 ethical affairs were in such a state in New York that the late Dr. Oliver White saw fit to send to the Comitia Minora of the county society a communication, from which I extract the following: "It is patent to us all, Mr. Chairman, and it is daily manifest, that members of our profession, once occupying honorable positions in it, have lost their standing among us by their own disreputable, dishonorable, and empirical practices, in violation of all medical ethics; and, inasmuch as we are not permitted by the laws of the State to discipline or expel unworthy members from the county medical societies, except through the courts; and, inasmuch as we deem it both just and proper that our county society should be the custodian of its own honor, and the conservator of its own morals—therefore do I earnestly entreat the Comitia Minora to draft a memorial to the Legislature of the State, praying that honorable body to grant the county medical societies throughout the State relief from the oppressive disabilities aforementioned; and that the Comitia ask the approval of the society to the proposed action in this matter."

The result of this action was the passage of the Medical Act of 1866, which gave the county societies almost plenary powers in matters of discipline. At the meeting of the county society, held June 4, 1866, a resolution was offered to the effect "that a committee of three be appointed to examine our list of members, and report the names of those whose connection with the society should be dissolved, and also what steps should be taken to accomplish this result." This resolution was referred, with others, to a committee of five, which met and considered the matters referred to them. This latter committee reported at the September meeting of the society that they could not purge the roll of membership as proposed, and recommended that "no further action be taken upon the matter at present," and requested "to be excused from further deliberation." This was certainly a rather impotent conclusion of the effort to purify the morals of the profession. Since then very little has been done in the way of attempting to check violations of the code.

This brings us to the year 1876, when the first open and bold proposal to repeal this code was made by Dr. J. Marion Sims, in his presidential address before the American Medical Association. From this address we extract the following:

"Here common sense and common interests have silently, almost imperceptibly, established a higher law that overrides the code and leaves it inert."

"The code of ethics is violated every day, either willfully or ignorantly, not only by the rank and file, but by men high in the profession—men who are considered leaders, advanced thinkers, and workers."

The proposition of Dr. Sims to abolish the code produced a profound sensation. Many thoughtful persons asked themselves whether the code as it existed, but unenforced, was doing any good, while others asked whether or not it was not doing absolute harm. It may be safe to say that by the majority Dr. Sims's proposition was looked

on with disfavor. At all events, no action was taken in support of it by the association at the time. This is not surprising when we consider the composition of this body, made up as it is of representatives from all parts of the country, very few of whom had examined the subject with any care. The hatred of sectarianism was so great that men seemed unable to calmly consider how it could be abated. Nothing was done. Shortly after this the writer found himself, as an officer of the county society, face to face with questions in ethics that must be met. The code was violated daily, both by those of high and low degree; but discipline was rarely asked for, except to gratify some personal malice. The two most obvious violations consisted in mixed consultations, and a striving after notoriety through the medium of the public press. These evils the officers of the society found themselves powerless to combat. This may appear to be a strange statement, but the facts are as follows: In reference to mixed consultations, the apparent spirit of the code was rendered nugatory by a change of base on the part of the homœopaths themselves. Their State society adopted a formal resolution,* in which they declared that for the future they would not adhere to the exclusive doctrines of Hahnemann, but would use such other methods as individually they saw fit. A careful comparison of this resolution with the consultation clause of the code makes it clear that the homœopaths had thus *technically* freed themselves from the ban, and that it would be impossible to discipline a member of the county society who should consult with them.

The second difficulty that embarrassed the Comitia was the matter of newspaper notoriety which certain members gained through "interviews," and through certificates given in favor of certain mineral waters, etc. This was a new form of impropriety, against which there was no provision in the by-laws of the society, and the Comitia were, therefore, powerless to take official cognizance of the matter. The president of the society, however, took on himself the burden of appealing personally to the offending members. Strange as it may appear, some of them referred him to the code of the American Medical Association, and claimed that their conduct was not only blameless, but praiseworthy. Curiously, an examination of this code appeared to support their claim. Under these circumstances, the Comitia had but one resource—namely, an appeal to the State society, in the hope that it would enact such laws as would enable the county societies to effectually deal with the evils referred to. Such an appeal was made to the State society, at its

session in 1879. It was disregarded, and no relief was afforded by the State society. The Comitia, however, were not altogether discouraged, and requested the writer to correspond with the chairman of the proper committee of the State society and ask him to make a personal investigation of the matters in question. A lengthy correspondence resulted. It was early conceded that the American code did not afford protection against the rapidly increasing certificate nuisance, and, if this ought to be stopped, some new and more effective rule must be adopted. The matter of consultations, however, presented much greater difficulties in the way of settlement, as on it hinged the whole question of sectarianism and its influence for good or ill on the profession. The present writer's views on the subject were presented in the form of a letter under date of November 28, 1879. From this letter I shall now quote at some length:

"The question" (of sectarianism) "is a grave one, and demands serious examination at the hands of the enlightened members of the profession, and never more so than at the present time. The subject must be looked at in its several aspects, and regarded from the standpoints of medical politics, of doctrine, of utility, and of its present *raison d'être*."

"In respect to the medico-political aspect of the question, it may be stated that the existence of sectarianism in medicine is a great evil, perhaps the greatest that at present oppresses the profession, and tends to injure it in the esteem and respect of the public. The State has seen fit to recognize three kinds of practitioners, who are in the position of public antagonists, each claiming that the general methods of treatment pursued by them are superior to those employed by the others, and each decrying and speaking in derogatory terms of the others. The public is not competent to decide to which of these the greatest measure of merit pertains; and, in the majority of instances, the choice of a medical attendant is the result of considerations that need not be entered into at present. The public, however, interests itself to a greater or less degree in the controversial elements of the question, and the result is a certain distrust of and lack of confidence in all three.

"The venerable Hufeland, nearly fifty years ago, in a very able essay on the subject, pointed out the evils that would result from sectarianism in medicine, and anticipated the statement made in the last paragraph. He wrote: 'Nothing is, on the whole, more prejudicial to our art, nothing tends more to diminish public confidence in it, than a *public quarrel*, and the *public expression of a mutual depreciation of one another by its professors*. All who have the honor of the art at heart must lament such open bickerings, and do all they can to prevent them. The public is only too disposed to interest itself and to find amusement in them. Has it not already come to such a length that our dissensions are paraded on the stage, just as in the time of Molière? And do we not feel that just as the estimate of our art in general decreases, so every one, to whatever party he may belong, loses somewhat?' . . .

"If, now, it be granted that sectarianism is an evil, does it not behoove the profession to consult together as to the

* *Resolved* That, in common with other existing associations which have for their object investigations and other labors which may contribute to the promotion of medical science, we hereby declare that, although firmly believing the principle *similia similibus curantur* to constitute the best general guide in the selection of remedies, and fully intending to carry out this principle to the best of our ability, this belief does not debar us from recognizing and making use of any experience, and we shall exercise and defend the inviolable right of every educated physician to make practical use of any established principle in medical science, or of any therapeutic facts founded on experiments and verified by experience, so far as, in his individual judgment, they shall tend to promote the welfare of those under his professional care."

—Adopted by the Homœopathic State Society, February, 1878.

best means to abate it? Before, however, this question is answered, it will be necessary to consider whether the abatement of this evil would bring about others that were still greater. The correct solution of this necessitates an acquaintance with a large number of facts, *pro* and *con*, which must be duly weighed, and the probable effects of any change in the present status carefully estimated. The opinion that I have personally formed is, that a certain amount of temporary inconvenience would ensue, to be followed by advantages that would more than counterbalance it. . . .

"If the abolition of legalized sectarianism is desirable, the methods of its accomplishment must be considered. To this end but two are known to me—namely, force and persuasion. Force has been tried, and has failed as regards the homœopaths. The more severe the exclusive enactments against them, the more they have seemed to flourish. The American Medical Association, in 1847, by the enactment of the consultation clause in the code, thought, by thus throwing odium on them, that the people would sustain the profession and refuse to employ the homœopath. In this the association was mistaken. . . . The action of the association, therefore, by excluding the early homœopaths from professional intercourse, simply caused them to unite the closer among themselves, each befriending and defending the other in time of need, and all uniting for the promotion of certain common objects, more especially the acquisition of the confidence of the people, and the attainment of governmental recognition. The measure of success that has attended their efforts we are all witnesses of to-day. It will, therefore, be readily granted that the policy of the association has not accomplished its object, i. e., the suppression of homœopathy, and I seriously question whether a continuance of this policy will not prolong and aggravate the present evils.

"Before, however, any other method be attempted, it is expedient that we should be accurately acquainted with the political and doctrinal status of the homœopathy, not of 1847, but of to-day, and we should more particularly regard the matter in its relations to the people and the profession of the State of New York. The homœopaths of this State may be divided into two pretty sharply defined groups. One group holds that the proposition "*similia*" is of great service in the selection of drugs where these agencies are requisite in the treatment of disease. They respect Hahnemann as a prominent promulgator of this doctrine. They reject, however, his theory of dynamization, they reject his peculiar views regarding the origin of chronic diseases, they reject his views as to dosage, and disbelieve or deny his statements concerning the efficacy of infinitesimals.* The other group of homœopaths pretend to hold strictly to all of Hahnemann's doctrines, and consider themselves his only genuine followers. An aggressive movement on the part of this latter party led the liberals

to a counter-movement, which resulted in the adoption by their societies of the resolution we have given above, and a decided split in their ranks.

"The regular profession has now an opportunity of settling the homœopathic difficulty in a very simple manner. Let it be understood that it is willing to receive into fellowship those who have practically abandoned Hahnemann's homœopathy, on condition that they also abandon the name, calling themselves, and permitting themselves to be called, *physicians* simply. It is probable that during the first year or so but a small number would avail themselves of the opportunity of joining the county societies. Later they would come in more freely. This would result in a return to the State of the chartered rights now possessed by them, and the removal of sectarian and offensive titles from the hospitals, dispensaries, colleges, and journals now controlled by them."

The above are the views that were held by me at the date that the above letter was written, and are in substantial accord with those that I hold to-day.

There is little doubt that, if this course had been pursued at that time, when the homœopaths were in so badly demoralized a condition, to-day there would have been no organized body, in this county at least, occupying an antagonistic attitude. The writer's position was, and is, that social and professional absolution be accorded to all who are willing to renounce exclusivism and unite with the main body of the profession.

In the number of this Journal for April 7th, pages 372 and 373, Dr. Flint would appear to be willing to go even further, and accord professional recognition to all, whatever their belief or practice, provided only they discontinued their connection with sectarian societies.

In our next we will continue the historical exposition of the subject.

SOME PRACTICAL REMARKS ON THE REMOVAL OF FOREIGN BODIES FROM THE EAR.*

By SAMUEL SEXTON, M. D.

It is not my purpose to go into any extended study of this subject, but I shall hope to draw attention to some practical points in the treatment of foreign bodies in the ear, drawn in part from my own experience. Of course, I have but little to offer that has not been already presented by other authorities, but a subject of the importance that foreign bodies in the ear very often assume in practice can not very well become too familiar to our minds. Although the expert may usually find but little difficulty in the removal of foreign bodies from the ear, unless, indeed, the case has been previously badly treated, yet the operation is not always simple to those who are generally the first to see them. It is to the latter that my remarks are mainly addressed.

As regards this trouble among adults, there need be but little said, since they are not in the habit of putting foreign

* "The homœopathy of to-day has also shaken from its feet the dust of more than one worthless theory. Although within its ranks are still numbered some so-called high dilutionists, its leaders have long ceased to insist upon infinitesimal dosage as an essential principle of treatment."—BEARD, "Popular Science Monthly," Feb., 1883.

* Read before the Medical Society of the State of New York, February 6, 1883.

bodies into their ears; and, unless the person is from some cause very nervous, their management is not usually difficult. To this statement one exception should, perhaps, be made—namely, that lunatics are well known to have the habit of stuffing cotton, wool, or pellets of almost any substance, into the ears, for the purpose, it is believed, of keeping out unpleasant noises. The habit of thrusting pencils into the ear sometimes is attended by the mishap of a separation of the mounting, an accident not often met with among women, for they usually employ a hairpin in scratching the ear—an instrument well adapted to the purpose if properly used. I have been frequently requested to remove pins which have been lost in the ear, and quite often an examination has failed to discover any. On one occasion, however, I found that the pin, which proved to be a short one, having slipped head foremost from the patient's fingers into the ear, had, after vigorous efforts at removal, been buried at the point well into the cartilaginous portion of the canal. The swollen integument made manipulations exceedingly painful. It was not deemed safe to seize the pin with forceps and liberate its point by pushing it back, for this maneuver would endanger the membrana tympani. But either this risk must be taken, or the integument of the canal must suffer certain laceration; the latter was regarded as the least of the two evils, and I therefore seized the pin, as far back as possible, with stout forceps, and, after lifting it up as far as the superior wall of the canal would allow, the point was elevated by a probe placed underneath; the exercise of slight force now secured its liberation.

The living insects and vermin which sometimes find their way into the canal are generally disposed of by syringing, as are also the larvæ which are developed in certain cases of otorrhœa.

Sea-shells and sand are quite often lodged in the ears of surf bathers, and in some instances the sand settles into the cul-de-sac formed by the downward curve of the canal where it joins the membrana tympani. I have found my foreign-body forceps of service in removing these small shells.

The class of cases, however, from their frequency and great practical interest, which are entitled to most consideration are children with small objects in their ears. To enumerate the various articles that have been found in the ears of young people would make a long list, including specimens from almost every department in domestic economy. I may be permitted to state here that it is not altogether an unnecessary precaution in these cases to first make sure of the presence of a foreign body in the ear before making efforts at removal, for it is well known that the ear has been often much injured by injudicious probing after fancied objects where parents were quite positive that a foreign body was present. The statements made concerning the character of objects is likewise misleading in some cases; thus, a child, two years old, was brought to me the other day, and I was shown quite a large oval-shaped porcelain button, with the remark that the child had put a similar one into the ear. The first examination convinced me that no such object was in the patient's ear; but there was found a piece of glass, which, fortunately, had not been disturbed by the family physician, to whom the case had

first been taken with the above puzzling statement. A bent silver probe was sufficient to dislodge the piece of glass without any injury to the ear, while the child was slightly anesthetized.

It seems scarcely necessary to urge upon any one the necessity of securing proper illumination before attempting any operative procedures in these cases; but, with a small forehead mirror, even a candle or any small lamp will afford light enough for an examination. A very good light, however, is required if an operation is necessary. I think it is a good plan in most instances to make the first examination without instruments, if possible; in this way we may decide whether an anæsthetic is necessary without alarming the child. I am very much in favor in these cases of placing the patient supinely upon a rather high table, while the operator occupies a low seat. This position is not only a comfortable one for the child, but, if the ear be turned downward as much as possible during manipulations, we have the advantage of the tendency of a loose body to gravitate downward. In cases where a loose object lies in the canal, the patient may lie quietly while a delicate hook—one improvised by bending a silver probe often does well enough—is employed

FIG. 1.

to gently pull it out, or the author's combined hook and curette may be employed (Fig. 2). But, should there be any struggling, one had better desist at once, for fear of pushing the object farther in, although there may be room enough to pass the bent probe or a steel hook between the object and the walls of the canal. The patient may now be forcibly held while a small but strong stream of water is thrown into the ear by a syringe, the stream being directed through the opening with sufficient force to carry the object out of the canal by the return current. I am in the habit of

FIG. 2.—SYRINGE FOR THE REMOVAL OF FOREIGN BODIES OR INFESTATIONS OF CERUMEN.

examining the ear after each syringe-ful has been injected, in order to ascertain the result of these efforts. Timid syringing here may be not only ineffectual, but it may even secure a further impaction of the object. It must, however, be borne in mind that even syringing is by no means always a harmless procedure, and that rupture of the membrana tympani may be thus caused. A case of this kind occurred in a patient who came to consult me from Alabama for a long-standing

otorrhœa. He informed me that the trouble had its origin in youth, and was due to the violent syringing done by a physician to whom he was taken for the removal of a foreign body from the ear. The instrument used was a large enema syringe, the first discharge from which knocked him down. The purulent discharge complained of was soon afterward established.

Should the foreign body entirely fill the canal, or should hooks or syringing be inadvisable, for the reasons stated, it is well to place the patient under ether before making attempts at removal, for a simple state of things may be easily converted into a complicated case where extraction is attempted in a struggling patient.

When accidents of this kind occur where the conveniences for giving an anæsthetic are not at hand, and proper instruments are also inaccessible, the foreign body should, I think, be let alone, unless the operator is sure of success, until every emergency has been provided for, not heeding the urgent demands usually made by parents and others for immediate action. Usually several kinds of forceps, a syringe, hook and curettes should be at hand, as more than one instrument is frequently required. In the greater number of cases the foreign body is easily dislodged by either curette or forceps; but should it be found that only by lacerating the canal in some degree could the foreign body be started, we may keep in mind the fact that usually the parts readily heal after very considerable injury has been sustained; and, therefore, if our object can be thus attained and all injury to the middle-ear avoided, we are, I think, warranted in acting with considerable energy. Let it be understood that I should only think of sacrificing to some extent the integrity of the canal in cases where the operation is sure to be completed, for afterward there will be swelling of the walls of the canal, the foreign body, if left, soon becoming tightly embraced, and the condition of the patient worse than if nothing had been done.

One word in conclusion concerning cases which are brought to the consultant after fruitless efforts have been made at removal. It has often been my experience to find that in such cases the foreign body has been pushed down upon the membrana tympani, which in too many instances has already been ruptured. The canal in these cases is usually found to be more or less lacerated and swollen. Where the membrana tympani has been ruptured, a discharge takes place from the middle-ear, and there is oozing of blood and serum from the walls of the canal when it has been wounded. Under these circumstances the operator must act with much caution, for the patient's friends are now even more urgent than at any previous time respecting the removal of the foreign body.

My first thought in these difficult cases is to, first of all, make sure that a foreign body is really present, for in several instances I have found the ear very much injured by efforts made with hooks, etc., to remove a foreign body where none was present.

If, however, the intruder is discovered, and lies against the membrana tympani, or very close to it, we can not always pass an instrument behind it without danger of rupturing the membrane. My own experience in these cases,

which has been considerable, is that, so far, since employing my foreign-body forceps, I have been fortunately able to remove such bodies by seizing them with the forceps and thus making traction. Should this be found impossible, rather than rupture the membrane by the use of hooks or curettes, I would advise delay in the majority of cases while attempts were being made to reduce the inflammation of the parts; for, when this has been accomplished, efforts at removal might be successful. When the foreign body lies at a safe distance from the membrane, one should, of course, avail himself of hooks or curettes as well as of the forceps, for they are often more serviceable.

Book Notices.

BOOKS AND PAMPHLETS RECEIVED.

Insanity: its Causes and Prevention. By Henry Putnam Stearns, M. D., Superintendent of the Retreat for the Insane, Hartford, Conn., etc. New York: G. P. Putnam's Sons, 1883. Pp. xii-248. [Price, \$1.50.]

A Manual of Auscultation and Percussion; embracing the Physical Diagnosis of Diseases of the Lungs and Heart, and of Thoracic Aneurysm. By Austin Flint, M. D., Professor of the Principles and Practice of Medicine and of Clinical Medicine in the Bellevue Hospital Medical College, etc. Third edition, revised. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 242.

How to Examine the Chest. A Practical Guide for the use of Students. By Samuel West, M. D., M. R. C. P., etc. Philadelphia: Blakiston, Son & Co., 1883. Pp. xii-200. [Price, \$1.75.]

Brain Rest. By J. Leonard Corning, M. D., formerly Clinical Assistant to the Manhattan Eye and Ear Hospital, etc. New York: G. P. Putnam's Sons, 1883. Pp. 103. [Price, \$1.00.]

Transfusion: its History, Indications, and Modes of Application. By Charles Egerton Jennings, L. R. C. P. Lond., etc. London: Baillière, Tindall, and Cox, 1883. Pp. viii-69.

Modificación de la Seccion Recto-vesical sin Lesion del Esfincter del Ano, de la Prostata Rudimentaria en este caso, ni de la Parte Membranosa de la Uretra. Por el Doctor Ernesto Below, de la Imperial Universidad de Greifswald. Mexico: Filomeno Mata, 1882.

Is Craniotomy Justifiable? By E. E. Montgomery, M. D., Obstetrician to the Philadelphia Hospital. [Reprint from the "Philadelphia Medical Times."]

The Opium Habit; its Successful Treatment by the Avena Sativa. By E. H. M. Sell, M. D., Fellow of the American Academy of Medicine, etc. Jersey City, 1883. Pp. 32.

THE DURATION OF MEDICAL STUDY IN GERMANY.—According to the "Union médicale," an association of physicians in Munich have petitioned the Federal Council to prolong the time of study required of candidates for the degree of doctor in medicine, stating that, whereas only four years are now demanded in Germany, the period of undergraduate study is five years in Austria, and six years in Holland and the Scandinavian countries.

MUSIC AS A THERAPEUTIC AGENT.—At the request of the chief medical officer of the military hospitals of Paris, a regimental band has been detailed to play at each of the three hospitals, one day in the week, for an hour. The hope is entertained that the effect upon the sick soldiers will be to hasten their convalescence.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 5, 1883.

THE NEW VOLUME FROM THE SURGEON-GENERAL'S OFFICE.

OFTEN as we have referred to the good work that has gone out to the world from the Surgeon-General's office, we think no apology necessary for giving prominence to a few words in praise of the surgical volume of the third part of "The Medical and Surgical History of the War of the Rebellion." Like the preceding volumes of this great work, the portion now before us, prepared under the direction of the late Surgeon-General Barnes, by the late Surgeon George A. Otis and Surgeon D. L. Huntington, forms part of a literary undertaking seldom exceeded in magnitude, and never, so far as our knowledge goes, in accuracy, in comprehensiveness of detail, or in thoroughness. It may be questioned if these volumes, side by side with those thus far issued of the "Index-Catalogue of the Library of the Surgeon-General's Office," have not done more than all other recent agencies combined to raise American medicine in the estimation of the world. Nor has this result been due solely to the literary skill with which the work has been done; unless there had been a great mass of observations and achievements worth recording and analyzing—the combined experience of hundreds of our colleagues called from all quarters of the country to apply themselves to the unaccustomed practice of military medicine, and of the little band of men that made up the medical corps of the regular army at the outbreak of the rebellion—no "Wizard of the North" could so have illumined the pages of the work as to make it, what it really is, the *chef d'œuvre* of military medicine.

The volume comprises Chap. X, on Wounds and Injuries of the Lower Extremities, over six hundred quarto pages; Chap. XI, on Miscellaneous Injuries, rather more than forty pages; Chap. XII, on Wounds and Complications, about two hundred pages; Chap. XIII, on Anæsthetics, twelve pages; Chap. XIV, on the Medical Staff and *Materia Chirurgica*, twenty-four pages; and Chap. XV, on Transportation of the Wounded, sixty-six pages. The reader's interest will center to a very great extent in the long chapter with which the volume opens. Although dealing largely in statistics and casuistics, and abounding in tabular matter, it embodies a great deal of analysis and reasoning of the highest order.

Like its predecessors, the volume is profusely illustrated with woodcuts, photographs, and lithographs, many of the latter being in colors. All of them are well adapted for the particular purpose in hand. Of the colored lithographs, plate XXV seems to us specially to be commended. It shows an inflamed knee joint laid open, displaying the articular surfaces of the patella and the lower end of the femur. Of the plain litho-

graphs, most of which we think more praiseworthy than the colored ones, we have been particularly struck with the beauty of plate LXX, showing four femoral involucra. Scarcely less meritorious are plate LV, giving two views of a femur as it appeared several years after the repair of a gunshot fracture at its upper portion; plate LXXII, representing two involucra of the tibia and fibula; plate LXII, giving a picture of the lower end of a femur with a musket-ball lodged in its medullary cavity; and plate LXIX, figuring four tubular sequestra of the femur after amputation.

We beg to congratulate the medical corps of the army on the progress of their great task. We need not assure them that their work is not in vain, for the one judgment of it everywhere is in the highest degree commendatory and appreciative.

THE ASSOCIATION FOR THE ADVANCEMENT OF THE MEDICAL EDUCATION OF WOMEN.

THIS organization was formed a few years ago, with the general idea, as we understood, that the medical profession of New York, which had frankly admitted women to its ranks, contained some gentlemen who were willing to go further, and, by means of such an association, comprising themselves, a number of the members of the faculty of the Woman's Medical College of the New York Infirmary, and a few non-medical persons who took an interest in promoting the practice of medicine by women, to give the college the benefit of their advice and assistance in its work. Contributions of money were made by the members of the association, sessions were held at which methods of instruction and ways and means of raising funds were discussed, and committees made elaborate reports on both these topics.

The association seems to have met with a very fair measure of success, if we may judge from a report recently issued in behalf of the executive committee by the president, Mary Putnam Jacobi, M. D., for it has been able to pay a professor of histology and a lecturer on materia medica, the latter serving also as a laboratory teacher of chemistry. The president is enabled to state, also, that "the large gynæcological clinics at the dispensary and infirmary afford opportunities for practical study in this especial branch of medicine such as are obtainable by no male medical students in this city."

As regards the moral success of the movement, she mentions "the encouraging signs of increasing liberality on the part of the medical profession in New York toward women in medicine. They are admitted at least in the audience of all the medical societies in the city, and to membership in all but—*mirabile dictu!*—the obstetrical. They are freely met in consultation; they enter freely into hospitals." We can not say whether or not women are excluded from the obstetrical section of the Academy of Medicine. If they are, the implied complaint conveyed in the exclamation "*mirabile dictu!*" we concede to be justified; but, if reference is made to the Obstetrical Society, it should be borne in mind that that is a private society, of limited membership, and that it does not expressly exclude women. If in individual instances women have applied for membership,

and have failed to be admitted, it is doubtless for reasons which do not at all imply that the members regard it as improper for women to belong to an obstetrical society. Something beyond the mere question of eligibility is always taken into account when an applicant appears before a private society. We therefore think that the president need not have felt compelled to score a failure for her association on the ground that no woman had yet been admitted to the Obstetrical Society. On the whole, it seems to us that those women who have chosen to become practitioners of medicine in New York have been accorded as fair a field as they could reasonably have hoped for.

SANITATION IN THE MISSISSIPPI VALLEY.

THE vexed question of details in the work of guarding against the spread of epidemic diseases in the valley of the Mississippi has, we trust, been materially advanced in the direction of a satisfactory solution by a recent meeting of the Sanitary Council of the Mississippi Valley, held at Jackson, Miss. We wish to acknowledge our indebtedness to Dr. J. H. Rauch, of the Illinois State Board of Health, for advance sheets of the proceedings. Although a voluntary organization, the association is so thoroughly representative of sanitary bodies in the West and Southwest that its action concerning such matters as it dealt with on this occasion may be taken as an earnest that there is now to be less clashing than heretofore in regard to the practical execution of measures designed to check the conveyance of infection through trade channels. This inference is strengthened by the fact that the meeting was attended by a number of gentlemen connected with the railway system and various commercial boards of the Southwest, several of whom took an active part in the proceedings.

The hope seemed to be entertained that the National Board of Health would be intrusted with the disbursement of the sum of a hundred thousand dollars appropriated by Congress to be expended in sanitary work at the discretion of the President and through such channels as he might determine, and the trust was expressed that harmony would be established again between that organization and the Louisiana board. The following memorial to the President was resolved upon:

We, a committee appointed by the SANITARY COUNCIL OF THE MISSISSIPPI VALLEY, at its fifth annual meeting, in the city of Jackson, Miss., April 3-4, 1883, do humbly but sincerely petition that the fund of \$100,000, to be used, with your approval, in the event of an outbreak of yellow fever or other epidemic disease on the coasts of our country, be placed at the disposal of the National Board of Health. That body can give confidence to the people of the Valley as to the necessary precautions and safeguards yearly demanded by the exposure of our Southern ports to the ravages of yellow fever. Their inspection stations and the mode their officers have adopted in isolation and disinfection, establishing quarantine only when emergency or occasion demands it, have earned for the National Board a degree of confidence that of itself alone is worth millions of dollars to the commerce of the country. To supplant this body or withhold from it the necessary funds to

maintain inspection stations at all exposed points will, in our humble judgment, clog the wheels of commerce by bringing about a feeling of distrust on the first alarm, be it true or false, and cause recourse to the shot-gun policy of quarantine, which can but prove destructive to the commercial interests of the Mississippi Valley, which in a measure affect those of the entire Union. With these views, submitted with full faith and appreciation of the solicitude you must feel for the welfare of the public health, we herewith subscribe ourselves your most humble petitioners.

We have accounts of a preference having been expressed by various sanitary organizations in the Southwest for a continuance of the Marine-Hospital Service in the management of the funds referred to, so that the question as to a choice between that service and the National Board of Health can not be considered as set at rest by the Sanitary Council's memorial, but it can be said of it that it is temperate and quite free from the air of truculence which has pervaded many of the resolutions by which some medical meetings have endeavored to bolster up the National Board of Health, and that it should tend materially to do away with the acrimonious feeling of which there has been some evidence on the part of certain sanitary bodies.

THE MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

NEXT Wednesday, as we briefly notified our readers last week, the Medical Society of the State of Pennsylvania will begin its thirty-fourth annual meeting, at Norristown. The address in medicine will be given by Dr. James Tyson, of Philadelphia, at the afternoon session of the first day, the address to be followed by five scientific communications. In the evening the president, Dr. William Varian, of Titusville, will read his annual address. At the Thursday morning session Dr. A. Craig, of Columbia, will deliver the address in surgery, and six communicated papers will follow. In the afternoon the address in obstetrics will be read by Dr. G. O. Moody, of Titusville, and the address in hygiene by Dr. Henry Leffmann, of Philadelphia. Five papers will occupy the remainder of the afternoon. On Friday morning Dr. John Curwen, of Warren, will deliver the address in psychiatry, which will be followed by three papers. At the afternoon session Dr. B. Lee, of Philadelphia, will present the report of a committee on the codification of lunacy laws, and three papers will conclude the scientific work of the meeting.

The list of papers volunteered is varied and attractive. Regretting that we have not space to enumerate them all, we will mention a few of those that are likely to prove specially notable, namely: On the duration of the protection afforded by vaccination, and on the efficacy of revaccination, by Dr. William M. Welch, of Philadelphia; on typhlitis and perityphlitis, by Dr. William Pepper, of Philadelphia; on the thorough removal of cancer of the breast, by Dr. S. W. Gross, of Philadelphia; on the medical service of lunatic hospitals, by Dr. Charles K. Mills, of Philadelphia, together with another on the same subject, by Dr. Samuel Ayres, of Pittsburgh; on surgical expedi-

ents in emergencies, by Dr. R. J. Levis, of Philadelphia; on the care of the hair, by Dr. J. V. Shoemaker, of Philadelphia; and on convallaria maialis, by Dr. Edward T. Bruen, of Philadelphia.

THE GROSS PROFESSORSHIP OF PATHOLOGICAL ANATOMY.

We learn from the "College and Clinical Record" that the Alumni Association of the Jefferson Medical College, of Philadelphia, has taken measures to found a professorship of pathological anatomy in the college, to be named in honor of the venerable Professor Samuel D. Gross. In these days, when one book supersedes another with such rapidity, it may not be known to many of our readers that in the earlier part of his career Dr. Gross wrote a treatise on pathological anatomy that for several years remained the standard American text-book of that branch of study. From this fact there is a peculiar fitness in the method determined on, quite apart from the general propriety that the alumni of the college in which Dr. Gross has labored so long and with such signal advantage to its interests should in some way devise means to honor his name so long as the institution continues in its course.

Dr. Richard J. Duglison has been made the custodian of the fund which is to be subscribed, and measures have been taken to bring the matter to the attention of all graduates of the school so far as they can be reached by circulars. In view of the possibility that this journal may be read by some of the alumni whose addresses are unknown to the trustees, we would suggest to them that they would do honor to themselves as well as to their alma mater were they to take part, without exception, in contributing to the realization of this most excellent plan. We have no doubt that they will do so very generally, and, in view of the great number of the alumni in various parts of the country, and of the *esprit de corps* that binds them to each other, thanks in great measure to our contemporary, there ought to be no possibility of a failure to obtain the required fund within a short time.

NEW YORK AS A MEDICAL CENTER.

WHEN one reflects upon the figures that we gave in a recent number of the journal and realizes that, in summing them up, very nearly 400,000 patients applied for medical relief at the various of our city and suburban charitable institutions during the course of a single year, the immensity of our present clinical wealth is fairly indicated. But we are not rich in numbers only. We excel also in density of disease, and our hospitals and infirmaries testify to it. But why should they not? Situated as we are upon the greatest of through lines between Europe and the populous countries of the East, there is a constant tendency for all intermediate points to furnish their quota to swell the aggregate of our population; and this concourse of nationalities reacts upon medicine, furthering the study of it by increasing the opportunities for clinical experience. Nor have physicians been slow in appreciating that New York is rapidly becoming one of the great centers of the world. At no time has there been a greater inpouring of out-of-town practitioners, and at no time have they shown a greater zest in seeking the advantages that are now so peculiarly prominent. And we are only just in crediting some of our medical colleges in this city with being

the first to conceive and organize a plan by which our clinical resources can be utilized in larger measure than has been possible heretofore.

The New York Post-Graduate Medical School, now entering upon another term of medical instruction, has been in existence about eleven months. Its birth was due to the fact that a body of active and professional men realized that the undergraduate medical schools of the city could not in their present status carry out a successful system of post-graduate medical instruction. It was founded without outside capital or appeal for lay support, and the substantial success of the scheme, we are glad to learn, is now assured by the members and quality of the matriculates, and its own financial strength. Equipped with a force of thirty-seven regular teachers and a score or more of auxiliaries, it has practically demonstrated that a practitioner may actually see a greater rarity of diseases in an ordinary seven weeks' course at the school than is often his lot during the prescribed term of his studies or in years of active practice. Resolutely admitting no undergraduates and conferring no degrees, the school has won the approbation of our medical colleges, whose teachers have given substantial proof of their satisfaction in its work by an assiduous attendance upon many of the courses. The embryonic physician who now leaves his alma mater, diploma in hand, may, therefore, receive the encouragement of his former teachers in entering upon his post-graduate instruction to complete the medical environment that will be necessary to fit him properly for his life-work.

As our columns have so often been devoted to the abuses of medical charities, it is worthy of note that this institution has solved certain elements of the question by devising a plan of medical relief that is satisfactory alike to physician and pharmacist. No patient is admitted for treatment if he can pay a physician's fee and buy his own medicines. Applicants are designated as worthy only when they are absolutely poor, or can pay a small sum for medicines. In such cases the charge for the medicine is adjusted by a regular scale. During the term just completed, we are informed that 5,568 patients have been rendered available for purposes of clinical instruction. This number, which indicates an average of over 900 patients a month, demonstrates that there has been no lack of material at command. We understand that this number could have been indefinitely augmented if it would have conduced to the success of the school. Almost all our prominent hospitals contributed more or less to a scheme that may now be said to be established upon a sound, substantial, and practical basis.

A CHOLERIFORM DISEASE IN MEXICO.

AT the late meeting of the Sanitary Council of the Mississippi Valley, Dr. J. H. Rauch, of Chicago, called attention to the prevalence of a cholera-like affection prevailing in some portions of Mexico, and suggested the necessity of vigilance on the part of the Gulf and Rio Grande authorities concerning the possibility of its spreading across the frontier.

RHABDO-MYOMA OF THE PAROTID GLAND.—In the "American Journal of the Medical Sciences" for April, 1883, Dr. T. Mitchell Prudden records a new case of a heterologous rhabdo-myoma, which presented some unique and significant features both in structure and in position. The tumor was intimately connected with and involved the parotid gland, and presented the usual peculiarities of structure of the rhabdo-myomata. In addition to this, it contained structures which the writer feels justified in considering as atypical rudimentary lobules of the parotid gland—atypical not only in structure and development, but in their distribution through and association with the incompletely developed muscular tissue.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

(Meeting of March 13, 1883, concluded.)

Dr. SANDS said that he thought the rule followed by Dr. Poore of postponing the operation of excision until the disease has reached a chronic stage was better than the opposite rule of early interference. As already remarked by Dr. Poore, the cases which are seen in hospital practice are usually of an aggravated character, and, as a rule, have already been subjected to the rest treatment, and often treatment by extension without avail, before they are admitted. He supposed, however, that all would agree that, until these milder methods had been found to be unavailing, excision should be withheld; for it was a fact that in private practice, where ample means were at our command, a very large number of patients with hip-joint disease recovered, either with entire restoration of the function of the joint in a few cases, or with ankylosis in other cases, thus obviating the risks attending excision of the bone. But, as Dr. Poore had remarked, when abscesses had formed and sinuses existed, and there was every indication that nature could do no more, and when by postponing an operation the general health of the patient became more impaired and secondary changes, in the liver and kidneys especially, became probable, excision seemed to be the only expedient to which surgeons could resort. It did not seem to him that the indications in hip-joint disease were different from those of disease in other joints in which there was no question with regard to the propriety of surgical interference. His experience corroborated Dr. Poore's in this particular, that usually there was very decided amelioration of symptoms after the performance of excision, and it would seem that this was more certain to occur now than formerly, when we paid less attention especially to drainage, and had not the advantage of antiseptic surgical dressings. He had operated twice within the last six weeks for excision of the hip joint. Both patients were children—one a girl six years of age, the other a boy nine years of age. Both had been under observation for one year, and had well-marked disease with abscess when they entered the hospital. In both the operation was postponed, in the hope that the abscesses would disappear, but the general health of the children began to give way, and it was very plain that the disease would proceed to an unfavorable termination if left to pursue its natural course. In both cases the acetabulum had been perforated, and the extent of destruction reached nearly as far as the level of the trochanter minor. In both cases the femur at the point of section showed signs of osteitis, and in both the improvement after operation was very marked, although in one more so than in the other. The boy, whose appetite had already entirely failed, and whose pulse was very rapid, improved so much that he was able to eat, immediately after the operation while his pulse was very much diminished in frequency. In the girl the shock of the operation proved severe for a few days, but after that her general health began to improve, and the improvement had continued. He thought that surgeons should not abstain from the operation because a radical cure was not very likely to take place. It seemed to him that the palliation afforded by the operation was sufficient to justify its performance. Respecting complications in bad cases, such as degeneration of the liver and kidneys, while it was a general fact that such complications were fatal, it occasionally occurred that the enlargement of the liver either diminished or disappeared entirely. He could recall one case, that of a lad twelve years of age, upon whom he operated in 1870, and in whom a very bad state of affairs existed at the time of the operation. There were extensive

abscesses and sinuses, and there was disease of the head of the bone and of the acetabulum—the latter, however, not perforated—and the general condition was such as to give but little expectation of a good result. But the wound healed, and, although afterward it reopened, no dead bone could be found. Finally, permanent closure took place about one year after the operation. Soon afterward the urine became albuminous, and two years later there was a very decided tumor in the abdomen, evidently formed by an enlarged liver. The boy had remained anemic ever since the operation was performed, and, although albumin still continued to be present in moderate quantities in the urine, the enlargement of the liver had disappeared, and the lad had grown to be a man, was now fairly well, and able to walk without any assistance except that derived from a thick-soled shoe. The parents were still living, and in excellent health. There was no hereditary tendency to tubercular disease.

Dr. J. C. HUTCHINSON remarked that a few years ago there was a great disposition to excision of the head of the bone in cases where it would seem that the patients would recover without it. The tendency, however, had turned in the opposite direction, and probably many cases which should be operated upon were neglected until it was too late. It seemed to him that, where the disease had resisted all the usual treatment, such as rest, extension, etc., and abscesses had formed, and the patient was gradually growing worse, and especially where there were some evidences of amyloid degeneration, the operation was clearly indicated. He had seen a great many patients recover under the most adverse circumstances, with ankylosis, of course, and sometimes the deformity was such as might subsequently be remedied by an operation.

Dr. BRIDGON had seen a number of cases like those reported by the author of the paper, and he thought that the majority of those in which perforation of the acetabulum had occurred terminated fatally. Cavities resulting from accumulations of pus within the cavity of the pelvis were difficult to drain. He had one specimen in which the perforation was large enough to have allowed the passage of the head of the femur, but it was not displaced in that direction. The most favorable result he had seen was in a case of a child eleven months old. The excision was done in the Presbyterian Hospital. One year after, the shortening was a little over a quarter of an inch. All the movements of the joint were free. The sinuses were closed, and the patient was now in robust health, and an inmate of the Institution of St. John'sland. In all the cases that he had seen, the patients were the children of tuberculous parents. In one case of long standing, in which the patient had recovered from the effects of the active process of the disease, he had judged that the caries had ceased, and that the numerous sinuses which refused to heal were kept open by the presence of a sequestrum. An explorative operation was done; the head and neck were gone; the acetabulum was filled with bony growth, in the center of which was an imprisoned mass of necrosed bone. In that case the sinus persisted for a long time after the removal of the offending cause. He had recently seen a young woman who was in the Presbyterian Hospital four or five years ago. All her sinuses had closed, and at times she could get about with tolerable comfort; but for a large portion of the time she was confined to her bed by pain. She had for some time suffered from diarrhoea, and he thought it possible that these discharges might indicate that the external sinuses had closed because the pus had sought an outlet through the acetabulum and rectum; but an investigation in that direction did not sustain the suspicion. Would not the symptoms in this case warrant an explorative operation?

Dr. SANDS asked Dr. Bridgon if he meant to say that the children in his cases had tubercular disease.

Dr. BRIDGON replied that all these children were the offspring of parents suffering from phthisis, and that, although in most of them there were no evidences of visceral tuberculosis, he believed that the caries was tubercular, and he was inclined to think that we were coming back to the idea that tubercle was the cause of many of the cases of disease occurring in the cancellous structure of bone.

The PRESIDENT remarked that, in deciding the question whether in any given case excision should be performed, he believed a much safer conclusion would be reached if the possibilities in these cases were always borne in mind. There was no case which was absolutely hopeless. Even cases in which perforation of the acetabulum had occurred and intrapelvic abscesses existed were not certainly and absolutely hopeless. In making up his estimate with reference to the result in any given case, he had been influenced in his judgment by one striking instance which he had seen—a young girl, in whom the operation of excision seemed to be entirely indicated, and to whom it was recommended, but refused, finally recovered, after languishing for a long time with numerous abscesses connected with disease of the hip joint. During the progress of the case, abscesses formed in the pelvis and discharged fecal contents, showing that there was communication with the intestine. The patient finally was able to walk upon the ankylosed limb, and many years afterward he saw her, and she had become a fleshy, healthy girl, with an appearance of the tissues about the hip joint which was somewhat remarkable. In her thin, emaciated condition, the soft parts, during the healing process, had become united to the bone opposite each fistula, and the interspace between, being gradually filled up with fat, left about the hip six or eight depressions, nearly as deep as the length of his finger, at points corresponding to those at which the old sinuses opened.

Dr. SANDS asked the President if he did not consider such a result as sufficiently rare not to justify the surgeon in accepting it as a criterion.

The PRESIDENT remarked that the result was extremely rare; nevertheless, the possibility of such an occurrence he believed should be accepted, and should have its due weight in the mind of the surgeon when considering any individual case.

STRANGULATED HERNIA.—Dr. GERSTER presented a specimen, and related the history of the case as follows. A working man, thirty-five years old, had had a reducible oblique inguinal hernia since his eleventh year, and had worn a truss for seventeen years. In the evening of January 30th, a sudden abdominal pain compelled him to leave work, whereupon he, of his own accord, took a large dose of salts and went to bed. Vomiting and more pain supervening, the family attendant was sent for, who made an unsuccessful attempt at taxis. Fecal vomiting, intense local pain, with tenderness all over the belly, induced Dr. Gerster to have the patient transferred to the German Hospital, where kelyotomy was performed, January 31st. Eighteen hours after the beginning of the incarceration, ether being the anæsthetic used, the very large, tense, and somewhat reddened tumor was incised in its full length down to the sac. This being opened, some reddish serum escaped, and a large omental mass presented itself, which was found to be firmly attached to the lowest portion of the sac. Both pedicles having been secured by catgut ligatures, this was removed, exposing about ten inches of small, much distended, dark-red intestine. The strangulation now was relieved by the usual steps. The strangulated portions of the gut were carefully drawn forth and examined. The knuckle of intestine showed no unequivocal signs of necrosis, was uniformly reddish-brown, not mottled or gray, its feel and turgor were normal both at the convexity and at the places of strangulation, the serosa shining, so that it was deemed proper

to replace it in the abdominal cavity. The sac, which was closed at its neck by a purse-string-like, strong catgut suture, including the external ring, was cut away below this suture, and entirely extirpated. The operation was finished by the application of a row of external sutures and an antiseptic dressing.

Immediately after the operation marked relief was felt, nourishment was retained, wind passed, and vomiting ceased. Five hours later the thermometer showed 103° Fahr., but the pulse was good, and the patient felt well. Next day some meteorism, slight nausea, and a temperature of 103.5° Fahr. were noted, wherefore one grain of opium hourly and an ice-bag on the belly were ordered. On the third day after the operation nausea and meteorism had still more increased, and the patient's skin and sclerotic had attained a marked icteric hue. The temperature ranged between 102° and 103°, the pulse between 110 and 120 beats. The patient complained of pain in the hypogastrium, which, however, did not increase on pressure. The wound was found well united and without a trace of reaction, so that some of the absorbed catgut sutures could be wiped away. The night was passed badly, in spite of large quantities of opium. On February 4th it was reported that the patient, having vomited last night, had a violent coughing spell, when he felt as though something had given way, but, not feeling any increase of pain, did not call the nurse. Next morning a knuckle of injected gut was found protruding from the open external wound; it had become firmly adherent to the walls of the wound by exuded lymph, and, in view of the meteorism, vomiting, high fever, and generally bad condition of the patient, it was decided not to disturb the protruding gut, but rather to make an attempt at utilizing the state of affairs. The finger was carefully introduced into the inguinal canal, and it was ascertained that no strangulation was present, whereupon a long incision was made into the gut, and, some gas having escaped, a soft catheter was pushed well up into the upper part of the intestine, this portion having manifested itself by the escape of fecal matter. Thus it was hoped that more gas might escape. The patient died the same day at 3 p. m., with all the signs of a most acute septicæmia. It was noted that as the rate of the pulse rose the temperature declined, till shortly before death the temperature was 99° Fahr.; pulse filiform, and not to be counted.

Post-mortem examination revealed the absence of septic peritonitis. A small quantity of orange-colored, clear serum escaped from the cavity. The prolapsed gut lying in the wound belonged to the lower part of the ileum, and showed signs of adhesive peritonitis. In the left iliac fossa a mass of agglutinated, slate-colored intestine was found, representing the hernial contents replaced at the operation. The places of strangulation were still clearly visible by a band-like depression at one end, and by a loss of continuity of the serosa at the other end of the knuckle. Here the tissues were not necrosed, whereas at the convexity of the knuckle, where at the operation normal turgor and feel were present, an extensive portion of the gut was necrosed and shriveled, but not detached. The intestine having been opened, a band-like coat of diphtheritic, grayish-white membrane was found closely adherent to the mucous surface corresponding exactly with the sites of strangulation. The mucous space inclosed by these two lines was covered throughout by a multitude of round and confluent diphtheritic patches, some of which, being denuded of their gray coating, presented themselves as shallow ulcers. These ulcers appeared to be the same both over the necrosed and the non-necrosed portions. The mesentery was found turgid and reddened, but not necrosed. The cause of death was acute septicæmia from enteric diphtheria and necrosis, caused by a strangulation of eighteen hours' duration, and probably favored by the action of the laxative.

Here we had, then, a case of very acute strangulation, where, at the operation for its relief, the gut was found to be without signs of imminent necrosis, fairly turgescient, and where, some five or six hours after the operation, that portion of the intestine necrosed which had not been subjected to the direct pressure of the strangulating ring. Clearly, changes in the arterial blood supply from the mesentery must have been the cause of this issue, and not direct pressure, as was most frequently the case. This was the second case of a similar nature occurring in the experience of Dr. Gerster, and he pointed out the insufficiency of our knowledge in determining at the time of celotomy whether the given intestine would or would not undergo necrosis after replacement. He called attention to the fact that the external appearance of the bernal contents in many cases presented no reliable signs for determining the future of such an intestine, and that the surgeon still had to trust to good luck. A narrowing down of the limits of this class of cases was very desirable.

Dr. BRIDGON said that some years ago he saw, in consultation with her physician, a German woman who had been suffering for nearly a week from symptoms of moderate strangulation. The right groin was occupied by a painful swelling. The skin was adherent to the subjacent structures, was red and inflamed, and fluctuation was distinct. On dividing the tissues, a collection of pus was found external to the sac, which contained a knuckle of intestine covered with granulations and only very slightly adherent to the ring. The stricture was divided, and the intestine was gently placed just within the ring. Everything went well until the seventh day, when, without the approval of her physician and at the suggestion of an officious friend, she took an active cathartic. It operated through the natural channel and through the operation wound which had been left open. The cavity of the peritonæum was not invaded. The fecal fistula gradually contracted and closed, and she got well.

He could recall another case of similar character which he had seen in consultation with Dr. Gillette. In that case there was suppuration of the sac, the gut was adherent to the neck of the sac, and it was sphacelated. The adhesions were not disturbed, the gut was opened, and the wound was left to close by granulation. Fæces were discharged freely through the wound, but the amount diminished gradually, the fistulous channel contracted, and eventually healed. Several years ago he presented at the Pathological Society a specimen of strangulated intestine which was removed from a woman in whom the condition of prostration did not appear to be warranted by the condition of the imprisoned gut, which was by no means much altered. The operation was followed by diarrhœa and death. He remembered that the late Dr. Krackowizer was present at the meeting, and expressed the opinion that death did occasionally occur after celotomy from catarrhal inflammation of the intestine due to the use of cathartics administered before the strangulation was relieved, and which only commenced to manifest their action after the obstruction was removed.

Dr. SANDS said there was one question which had not been broached in connection with the specimen presented by Dr. Gerster. He thought it was the rule with most surgeons in doubtful cases to be careful to leave the suspicious portion of intestine at or near the abdominal ring, so that in the event of necrosis an artificial anus would be likely to be established. He supposed that in the present state of our knowledge this was a proper rule. He could recall instances similar to those related by Dr. Bridgon where he had returned the intestine in this way, which subsequently became necrosed and led to the formation of an artificial anus which finally closed spontaneously. In Dr. Gerster's case it would seem that death was not determined by peritonitis caused by the reduction of the intestine,

but probably by septicæmia resulting from gangrene, which would have occurred equally if the intestine had not been reduced. This circumstance raised the question whether it might not be thought advisable to excise that doubtful portion of the intestine and unite the edges of the remaining portion with sutures. This operation had been proposed and performed in cases where gangrene was manifest, and although theoretically such a procedure was correct, yet experience had shown that the adjacent intestine was apt to be so much softened as not to be able to bear the strain of the sutures. Perhaps, however, in cases like the one narrated by Dr. Gerster, in which the morbid process had not far advanced, success might be possible.

Dr. WEIR remarked that in cases in which gangrene was recognized the surgeon at once knew what to do. He was either to establish an artificial anus or excise the intestine, preferably the former. In the doubtful cases it might be very difficult to decide which course to take, whether to cut off the strangulated portion of gut altogether, since the present specimen showed, with others he had seen, that there was risk of subsequent gangrene, or to partially replace it, as already mentioned, and await the result. In one instance he had encircled the intestine with a loop of catgut—the ends of which projected from the wound—to keep the intestine in the neighborhood of the ring. The case, however, did well, and no use was made of this loop, which dissolved in the discharges.

The PRESIDENT remarked that he had been guided chiefly by the condition of capillary circulation in answering the question whether or not the vitality of the gut would be retained. If, after pressure with the fingers, the return of the circulation was feeble and imperfect, he had always felt that the intestine was doomed to die.

Dr. GERSTER thought we were unable in every case to apply satisfactorily the test mentioned by the President, as in many cases the gut was so engorged and thickened that pressure could only be made so far away as to be of no special value for determining the exact condition of the circulation in the portion which had been strangulated.

The PRESIDENT replied that he had always been able to decide the question satisfactorily for himself after freely dividing the stricture; and he thought that, by the exercise of a little patience, the condition of the capillary circulation could be ascertained.

Dr. WEIR exhibited an instrument devised by Mr. Treves, of London, for suturing divided ends of intestine after the removal of a gangrenous or diseased portion. The details of the instrument are to be found in the "British Medical Journal" for December 12, 1882.

THE OVARIAN CORPUSCLE.—Dr. BRIDGON presented a specimen of fluid removed by aspiration, for diagnostic purposes, from a tumor in which there was doubt as to the true nature of the disease. The whole abdomen was filled by an elastic but non-fluctuating tumor. The history gave no clew as to what point it started from. It was immovable, and its connections, if any, with the uterus could not be made out. The fluid was of the color and consistence of golden syrup, was alkaline in reaction, and its specific gravity was 1.014. Heat transformed it into a coagulum, which was dissolved by boiling with two volumes of acetic acid, determining the presence of paralbumin, regarded by some as significant of ovarian disease. Under the microscope he found some few epithelial formations, and a number of large round-granular corpuscles, also considered as pathognomonic of ovarian cystic growths. In conjunction with this, Dr. Bridgon presented a specimen of fluid which he had removed the day before from the tunica vaginalis of an old gentleman. This he also treated by the chemical test applied to the first specimen, and demonstrated the presence of paral-

bumin. Continuing the examination, he found under the microscope the same large, round granular corpuscles, monster leucocytes.

A STATED meeting was held March 27, 1883, T. M. MARKOE, M. D., President, in the chair.

PIROGOFF'S OPERATION.—DR. GERSTER presented a patient upon whom he had performed Pirogoff's operation. The man had suffered seven or eight years from osteitic disease involving nearly all of the tarsal bones. He had been subjected to a great variety of treatment, and finally Dr. Gerster proposed this operation, which he performed in the ordinary manner five weeks ago. The os calcis was not wired to the tibia, but union between the bones took place by first intention. The man was able to stomp around the ward on the seventeenth day after the operation. There was one inch and a quarter shortening.

DR. H. B. SANDS then read a paper on *THE QUESTION OF TREPHINING IN INJURIES OF THE HEAD*. [Dr. Sands's paper will be found in this journal for April 21st, p. 423.]

DR. POST referred to the case of Dr. Van Sinderen, who, when a boy, was kicked on the head by a horse. A portion of the cranial bone nearly as large as the hand was removed from one side, and pulsation could be felt, as in one of the cases presented by Dr. Halsted. He grew up to manhood, studied and practiced medicine, and finally died of cerebral disease following the loss of a member of his family.

DR. POST also referred to two cases of compound fracture of the cranium which he had recently seen in hospital practice. The first was that of an Italian twelve years of age, who was injured by a fragment of stone thrown from the roof of a house, producing a depressed compound fracture. The loose fragments were removed, the depressed portion was elevated, and the boy recovered perfectly.

AT nearly the same time a child fell from the third or fourth story window and received a complicated injury. There was extensive compound fracture of the skull, with depression, fracture of the thigh, etc. Dr. Post elevated the depressed portion of bone, but the shock was so great from the complicated injury that the patient died the next day.

IN another instance a child fell from a moderate height, and, after being a little dazed for a time, recovered its senses so as to be able to walk and to talk, but in the course of half an hour it became completely comatose. It was supposed that intracranial hemorrhage had occurred, and he trephined the patient, but did not find any blood at the seat of the injury. To his surprise, however, the coma passed away and the child recovered. At nearly the same time he had a case of almost precisely the same character, in which the patient recovered. He had supposed that the occurrence of coma half an hour or an hour after the receipt of the injury was pretty certain evidence of hemorrhage, but in both these cases recovery took place after trephining, and yet no hemorrhage was found.

DR. L. A. STIMSON, in reply to Dr. Sands's request for the expression of the society with reference to the rarer methods of treatment, narrated two cases, one of compound fracture without trephining, and one of simple fracture with trephining. The first case he saw in Bellevue Hospital. A young man came on foot one morning, having received a blow upon the back of the head, a little to one side of the median line, inflicted by a chisel. The wound was a linear one, the bone was penetrated, and one edge of the cut portion of the skull turned outward. There were no head symptoms. The man remained in the hospital for a week or ten days without symptoms. Suddenly, without any warning, severe cerebral symptoms developed and the case terminated fatally within a few hours. At the autopsy there was found an incised wound in the soft parts and in the bone, with

very slight splintering of the inner table. The dura mater was not injured. There was an abscess of about the size of a hickory nut in the substance of the brain, separated from the dura mater by a layer of healthy brain tissue. There was a small amount of pus and serum between the dura and the bone at the point of fracture. Death was apparently the result of the inflammatory processes in the wound, and of its insufficient drainage.

The second case was one of simple fracture treated by trephining. A young man fell from a truck, and was removed to the Presbyterian Hospital in a comatose condition. Dr. Stimson saw him twenty-four hours after the receipt of the injury. The patient was still comatose. There was no wound of the scalp, and only a slight puffiness on the left side of the head, which the house surgeon said was not present when the patient was admitted to the hospital. There was slight weakening of the left forearm. There were no other symptoms. On the third day after the injury he received word that the patient had had several violent general convulsions, and, on visiting the hospital, he found him comatose, with high fever and considerable agitation, and with very decided paralysis of the extensors of the left forearm. Dr. Stimson made an incision upon the right side of the head along the motor area, and found a long linear fracture running from behind forward, parallel to and about three inches from the median line, with slight separation, but no depression of bone. He applied a small trephine at the site of the fracture, removed a button of bone, and found a thin layer of clotted blood between it and the dura. He enlarged the opening in the bone posteriorly, and the dura bulged into it, but was without pulsation. He then applied the trephine a second time, about one inch anteriorly to the spot where the first opening was made, removed a button of bone, and found a clot as before, and the dura also bulged. He then introduced the needle of a hypodermic syringe, and withdrew a small amount of fluid blood, after which he nicked the dura and evacuated about a drachm of blood, which may have come, however, from a vein wounded by the needle. The patient had no more convulsions. Toward the end of the operation he seemed to be more sensitive to the handling of the wound than at first. Afterward he developed complete facial paralysis on the right side, and died on the following day. No autopsy was allowed.

While he did not think that the soft parts should be divided in cases of simple fracture, or the bone trephined without positive indications, still he did not think this operation a grave one if the dura were left uninjured. It seemed to him that interference in each case must be decided by a comparison of the possible benefits with the risks of the operation. In illustration of interference based on such comparison he mentioned a case as follows: A woman had been insane for nearly two months after falling out of a second story window and receiving a scalp wound behind the motor region on the right side of the head. He trephined and explored for cerebral abscess. The dura was not opened. No evidence of abscess was obtained. The patient recovered from the operation, and also from her insanity, within a fortnight. As in this case the grave mental disability seemed to justify the operation, even in the absence of probable symptoms of abscess, so in another grave case cerebral symptoms might make it proper to change a simple fracture into a compound one in order to remove a depressed fragment or a clot.

DR. J. L. LITTLE referred to a case which came under his observation a few years ago at St. Vincent's Hospital. The patient fell from a height and received a slight scalp wound, which exposed the left side of the frontal bone about one inch above the angle of the eye. Exploration showed simply bare bone without any evidence of fracture. The patient's symptoms

were those of insanity, and she became so violent that at the end of six weeks it was arranged to have her removed to a lunatic asylum. Before leaving the hospital Dr. Little trephined and removed two buttons of bone, and also the bridge of bone which connected the two openings, but found nothing wrong. The inner table of the skull was perfectly normal. In less than twenty-four hours there was marked improvement in the symptoms, and within two weeks after the operation the patient left the hospital perfectly sane.

Dr. Little further referred to a case which he saw a few years ago in consultation with Dr. Van Wyck. The patient was a child about seven years of age, who had received a compound fracture of the right parietal bone. There being no symptoms of injury of the brain, no operation was performed. About four weeks after, when Dr. Little saw it first, the child was suffering from symptoms of compression, paralysis, dilatation of the pupil, coma, and convulsions, and had had several severe rigors. The wound was granulating. Dr. Little enlarged the wound and removed several loose pieces of bone. There was no marked depression of the fragments. The symptoms of compression evidently not depending upon depressed bone, Dr. Little ventured to puncture the dura, but, finding nothing, he then punctured the brain substance with a delicate bistoury, and found an abscess some distance below the surface. About a drachm and a quarter of pus made its escape. The symptoms of compression rapidly disappeared. A fungus cerebri took place which was treated by the application of dry absorbing powders and moderate compression. The child made a good recovery.

Dr. Post referred to an autopsy in the case of a little girl at which was found a depressed fracture of the skull, moderate in amount, that had not been attended with marked symptoms in the beginning. But, after the lapse of several weeks, symptoms of encephalitis had come on, and had led to a fatal result. An abscess was found in the lower part of the frontal lobe on the side corresponding with the injury, and in the immediate vicinity of the depressed bone.

Dr. SANDS remarked that he did not wish to be understood as being opposed to trephining in every case of simple depressed fracture. He merely wished to say that, as such fractures were usually the result of a force applied over a considerable area, the lesions were liable to be extensive and of such a character as to render trephining a useless operation; consequently, he would hesitate before converting a simple into a compound fracture. But, if he believed that the fracture was limited in extent, and that mischief might be directly caused by a fragment of bone pressing upon the dura, he would not hesitate to trephine. He thought, however, that such cases were extremely rare.

The PRESIDENT said that his own experience accorded nearly with that of Dr. Sands. He had thought that it was, as a rule, disastrous to add to an already existing fracture the complication of an external opening. In one or two instances where he had felt that the depression was abrupt and very marked, and that the symptoms were due to the depression, he had made an incision and proceeded to elevate the bone, but the cases of abrupt depressed fracture without breaking of the skin were very rare. In only one or two instances had he ventured to trephine, and he was not able to give the results. He believed that the true principle was that which Dr. Sands had announced.

Dr. STIMSON referred to a case which illustrated the application of the principle advocated by Dr. Sands and Dr. Markoe. It was one of simple depressed fracture produced by a blow with a hammer. He had already reported the case to the society. The patient was trephined, and made a good recovery. There were no brain symptoms.

The PRESIDENT remarked that in such a case the indications for trephining seemed to be very clear. Besides, if there were symptoms which seemed to depend especially upon the local injury, trephining should be performed.

Dr. SANDS remarked that, in simple fracture accompanied with deep depression, recovery sometimes took place without trephining. He had seen an example of this kind many years ago in the Massachusetts General Hospital.

Dr. J. L. LITTLE presented A FOREIGN BODY REMOVED FROM THE ESOPHAGUS. It was accompanied by the following history: The patient was admitted into St. Vincent's Hospital on February 28th. On the night before she accidentally broke a plate containing two false incisor teeth. She placed the broken plate in her mouth before going to bed. On awaking in the morning the pieces became loose, and one of them slipped down into the esophagus. On entering the hospital, the patient complained of the following symptoms: Pains between the shoulders, and just below the clavicle on the right side; was unable to swallow liquids, the attempt giving rise to severe pain; had had slight hæmorrhage from the throat. Upon examination, she complained of great pain upon pressure over the esophagus, just above the clavicle, but no indication of a foreign body could be felt. A digital examination, and the introduction of Cusco's laryngeal forceps, failed to detect any obstruction. Dr. Little then introduced a probang with a rounded steel hook at its extremity. This was passed down about six or seven inches below the tongue, and came in contact with the foreign body. He succeeded in hooking it, and in making strong traction; but, failing to dislodge it, he unhooked it, and, after several unsuccessful attempts, finally succeeded in dislodging it. The patient then stated that the body had slipped down farther into the esophagus. He instantly introduced the hook, and was so fortunate as to catch the body again and to draw it up until it was in sight. The hook then slipped off, and the plate slipped down again. He then quickly introduced an esophageal forceps, and succeeded in seizing and removing it. The plate removed contained one tooth, was of a triangular shape, measuring one inch and seven eighths in one direction, and one inch and one fourth in another. A slight amount of hæmorrhage followed the removal. The patient was able to swallow with some pain immediately after, but left the hospital the next day.

Dr. W. T. BULL referred to two cases in which he had removed similar foreign bodies from the esophagus with the ordinary "coin catcher." The first was that of a patient who, nine days before admission to the hospital, swallowed an upper plate containing two front teeth, and took nothing afterward except fluid nourishment, and that with much difficulty. He said he had lost twenty-five pounds in weight. The foreign body had lodged in the esophagus just above the entrance to the stomach, and could be pulled up to about the level of the cricoid cartilage without difficulty, and then it would disengage from the instrument and fall back. Dr. Bull then resorted to the following manoeuvre. He introduced two coin catchers, one beyond the plate, the other just below the cricoid cartilage—to "lie in wait." With the first the body was drawn up until it was arrested, when the second caught it at once and it was removed.

In the second case the rubber plate—a small one—was easily caught with the coin catcher, just within the entrance to the esophagus, and removed at the first effort.

SECONDARY HÆMORRHAGE AFTER LIGATION OF THE FEMORAL ARTERY.—Dr. Post continued the history of the case which he reported four weeks previously, one in which secondary hæmorrhage occurred after removal of a sarcoma of the thigh, and in which he ligated the femoral artery. Subsequently hæmorrhage occurred, which he thought was evidently from the distal side. Believing it to be unwise to open the wound and to ligate

the vessel, he applied a compress, with a bandage from the toes upward, and suspended the limb, and this method was effectual in restraining further hæmorrhage. The hæmorrhage had not recurred, and the patient was doing well.

Reports on the Progress of Medicine.

QUARTERLY REPORT ON ANATOMY AND PHYSIOLOGY.

No. IX.

By WILLIAM C. AYRES, M. D.

MENSTRUATION AND ESTRUATION.—In one of his lectures on the comparative physiology of menstruation, Wiltshire, of London ("Brit. Med. Jour.," March 3, 1883), after going over a good deal of ground which is more or less familiar to us, adds: In all creatures there are periods of "heat" or sexual excitement when both males and females are apt for procreation. These periods are marked by a systemic excitement, and by local phenomena of a more or less conspicuous character. Among the mammalia, the times of heat display a seasonal periodicity; that is to say, they recur annually, biennially, quarterly, or at more frequent intervals, according as the conditions of existence or environments are favorable or the reverse, and, apparently, in some degree according to the size of the creature, being, for example, rare in the elephant. Yet in every creature seasonal periodicity, at longer or shorter intervals, is observed, and, as Darwin and Laycock have shown, this periodicity always partakes of a hebdomadal character. It is always some greater or lesser multiple of a weekly period.

In the lower animals, in a wild or feral state, the aptitude for procreation is seasonal, recurring mostly at times when food and warmth are plentiful. Under normal circumstances, the earliest longing for sexual congress is promptly gratified in the female, conception ensues, gestation proceeds on its appointed course, and, until the genesial cycle has been completed by parturition, the "rut" or "heat," with its attendant desire for copulation, does not ordinarily recur. But, impregnation failing from any cause (e. g., absence of the male at the appropriate season of sexual appetite), we may inquire, Do the symptoms of heat persist indefinitely? and, if not, What period elapses before they are again exhibited? Observation of wild animals, both in a state of nature and during captivity (when the latter does not interfere with reproduction), and, still better, of domesticated animals, shows that, after a definite period of quiescence, estruation, or the "rut," invariably recurs at epochs which strictly conform to some multiple of the week. In highly bred and well-cared-for domesticated animals, estruation would probably be renewed periodically until arrested by conception; for it is well known that domestication enormously enhances the capacity for reproduction, and renders that sustained which under other conditions of environment subsides until it is renewed by the seasonal awakening. It is probable that, in the wild state, in the absence of the male the "heat" stimulus to sexual desire would, after a few periodical manifestations, die away, grow cold, and subside, remaining in abeyance until the return of the season with which it is primitively allied. The long rhythmical periodicity may be termed "seasonal," since it appears to be primarily allied with, or dependent upon, seasonal changes, as has been abundantly demonstrated by Darwin, Herbert Spencer, Laycock, and others. This seasonal periodicity of "heat" accounts for a corresponding periodicity in

delivery; for, as is well known, many wild animals bring forth their young at mild and favorable seasons, as spring, and not at inclement or unfructuous times. This is generally so in our domesticated animals when art does not interfere with the natural instincts; and, in truth, this primitive seasonal condition of the exercise of the generative function underlies the process of reproduction, even in the highest creatures. A trace of this seasonal influence is certainly still conspicuous in the greater tendency manifested by the human female to conceive at certain annual epochs; and it seems probable that this seasonal influence underlies the genesial function in all creatures, and is a relic and trace of a primitive or primordial condition governing reproduction. We shall see that not only does woman most frequently begin her menstrual life in the summer months, but she brings forth her offspring more frequently in the spring than in other seasons, just as the lower animals do. Many years ago the author concluded that every woman had a law peculiar to herself, which governed the times of her bringing forth (and conceiving); that, in truth, she was more prone to bring forth at certain epochs than at others; and subsequent researches have not only abundantly confirmed his surmise, but established the accuracy of the forecast. The evidence is given in other lectures.

The influence of civilization and domestication in expanding the reproductive powers is conspicuous. And yet the generative system, as Mr. Darwin has ably and conclusively shown, is highly sensitive to changes in the environment of the individual. Seemingly, the higher mental endowment of advanced human beings carries with it not only an augmented capacity for the reproduction of their own species, but also bestows a like advantage upon the creatures showing amenability to man's sway by flourishing under his dominion. Not alone does the human race increase, but man's flocks and herds multiply prodigiously. Would that the same care were observed in the breeding and propagation of the human species, the author adds, as in that of animals of merely commercial value!

The influence of domestication upon the fertility of animals amenable thereto is most instructive. The total productiveness of most of them is enormously increased thereby. The continuous and regular supply of food, the artificial warmth, selection, care, and culture bestowed on them greatly enhance their productiveness. Puberty not only arrives earlier, but a sustained power of reproduction is acquired; more offspring can be bred, and these again breed earlier. The manifestations of "heat," therefore, instead of being confined to seasonal appearances, are much more frequently renewed, resembling, be it noted, those in women; and where indulgence is denied the female, as it is for commercial purposes in the case of cows, for example, by segregation from the male, the periods of heat may be observed to recur with marked regularity—in cows usually every three weeks. Domestication, then, increases the fertility of domesticated creatures, while seclusion from the male, either for economic purposes or through captivity, permits the repeated exhibition in the female of the phenomena of rut or heat, whatever they may be.

Prolonged civilization has done for women what domestication has done for the lower animals; it has augmented their power of reproduction, made them more prolific, and rendered more frequent the manifestations of that aptitude; hence the sustained repetition of oestro-menstruation. Darwin ("Descent of Man," p. 45) has remarked that savages appear to be less prolific than civilized peoples. Bischoff has truly said: "If women menstruated only once or twice in a year, it would long since have been remarked that such was the only time when conception was possible; menstruation would long ago have been recognized as perfectly analogous to the 'heat' in animals, even

though the most essential element of it, the maturation of ova, had not been discovered." He also says: "The ova form and become mature, and are extruded from the maternal organism, usually at fixed periods, having regularly recurring intervals." This is the period of "heat" in animals and "menstruation" in human females. The analogies existing between menstruation in women and estruation in the lower animals may be shown. In both there is special aptitude for conception at or near these times, though women are more highly endowed, inasmuch as they may conceive at epochs somewhat remote from this "period." The lower females will rarely permit intercourse except at the period of heat, which in ruminants, at any rate, are of brief duration; indeed, the males seldom attempt it during the intervals. This is unlike the practice of human beings. In both it has been shown that germ-cells are then ready for impregnation; though here again woman enjoys the advantage implied above, in that ova may be produced at times other than those of the "heat," that, however, being admittedly the usual and ordinary epoch for that ripening and debiscence. Propinquity to the male, without access to him, is known to hasten ovulation in birds; and in the human female repeated sexual indulgence may stimulate the rupture, if no more, of Graafian follicles. One should not lose sight, however, of the superior evolution of the sexual system in the higher creatures, for this may not be without influence upon the process. It can hardly be maintained that sustained ovulation is the exclusive appanage of the higher animals, but there can be but little doubt that the organic superiority of the highest enables them to co-ordinate more rapidly the advantages their endowments and environments may chance to afford; their sexual superiority is correlated with their mental as with their general organic superiority, etc. He then gives some facts about the comparative anatomy of the uterus and ovaries, etc., which are well worth calling to mind.

GAUTIER'S POISONOUS SALIVARY ALKALOID.—In his article on a certain alkaloid in the human saliva ("Arch. f. path. Anat. u. Physiol. u. f. klin. Med.," xci, 1, 1883), Bujwid makes a communication on the salivary alkaloid described by Gautier ("Gazette hebdomadaire," No. 29, 1881), which does not resemble an albuminoid. According to Gautier, this alkaloid should possess the following properties: It is not soluble [in what?], it is not destructible by boiling, and gives crystals when treated with gold and platinum chlorides. As to its physiological action, it behaves like those alkaloids which are found in the cadaver; when brought into the system, it acts like serpent's venom, this action being most marked when it is given to birds. Gautier makes no further mention of the nature of the alkaloid, of the method of obtaining it, or of the quantity requisite to produce the effects.

Bujwid's communication is in respect to the latter questions, the first of which was to determine the quantity of the substance which, when introduced into the system, would produce death, or, at least, an appreciable effect. He experimented in the following way: He boiled the saliva of a healthy man of twenty-five years, and then collected 100 cc., evaporated it as much as possible, and treated the residue with alcohol. After washing with alcohol and water very often, he evaporated it to about 2 cc., and used this as a subcutaneous injection. In the first experiment he injected as much as is contained in 15-30 cc. of saliva into a pigeon, and also into a frog. They both showed, one hour, and, indeed, several hours after the injection, no change in their condition. In the second experiment he used, in the case of a pigeon, as much as was contained in 50 cc., and afterward, also in a pigeon, as much as was obtained from 100 cc. of saliva. In all three of these experiments there was no apparent effect. In the last pigeon the rectal tempera-

ture was 42.4° C. before the experiment; one hour after it was 41°, and the next day 41.3°.

His experiments show, therefore, that in the fresh saliva, in as large a volume as 100 cc., there is not enough of the supposed alkaloid of Gautier to produce either death or an appreciable effect, even on a small animal.

AUTOMATISM DURING HYPNOTISM.—In their article on certain cases of cerebral automatism observed in hysteria during the cataleptic period of hypnotism ("Jour. of Nerv. and Mental Disease," Jan., 1883), Charcot and Richter make some interesting observations. First it is shown that the patient is really hypnotized. This they do by means of a tambour (see the original) attached to an extended limb, the object being to register the smallest oscillations of the member, while, at the same time, a pneumograph applied to the chest gives the curve of the respiratory movements.

In the case of a cataleptic, the lever which corresponds to the extended member traces a straight and perfectly regular line during the entire duration of the observation. In the case of the simulator the tracings resemble those of the cataleptic for a short time, but at the end of a few minutes the line is not regular, but broken into a series of larger oscillations. In this way we can tell whether the person is feigning or not.

The respiratory curve in the simulator also shows the rapid changes which occur in consequence of muscular fatigue from holding out the arm, whereas that of the cataleptic shows that his breathings are infrequent and superficial.

Their facts of cerebral automatism they gather from certain experiments, among which was localized faradization of the muscles of the face, according to the process of Duchenne. In their first experiment they saw the attitude of the body, and the appropriate gesture, succeed to the expression imparted to the physiognomy by the electric current. [The current does not interfere with the cataleptic state.] When by reason of uncertainty in the operative procedures the physiognomy did not give clear indications, the attitude or gesture also remained undecided. When the current was removed, neither the face nor the body changed in the least, and the cataleptic was left in the condition of a living statue, which often displayed striking expressions capable of being used by artists to great advantage. The cataleptic will retain such an expression until the arms, for instance, are placed vertically, when the face will assume an indifferent expression.

The main interest attached to these experiments is not that the phenomena are singular and unexpected. It lies, on the contrary, in this, that they are intimately connected with the normal action of the nervous system, and their principal merit is to throw into relief, by reason of their isolation, facts whose trace is not difficult to find in the normal state. Thus, these experiments in hypnotism become a most beautiful demonstration of the automatic action of a part of the encephalon, an action already described by psychologists and physiologists, and to which has been given the name of cerebral automatism, or unconscious cerebration.

THE CORPUS STRIATUM.—In the same journal Dr. A. L. Ranney gives a condensed review of our knowledge of this important portion of the brain, and, besides, prints a diagram which is well worth the time necessary for understanding its meaning, since it shows in a conspicuous manner the relation which the corpus striatum has to the rest of the brain.

His figure 3 is the diagram which represents the afferent and efferent fibers of the corpus striatum. It shows very clearly the connection between the caudate nucleus and the lenticular nucleus, with the psycho-motor region of the cortex; also the connection of the peduncular fibers with the lenticular nucleus,

the fibers of the so-called "internal capsule," and, further, the olfactory fibers connecting with the caudate nucleus. The diagram is ingenious.

Letters to the Editor.

A STATEMENT BY DR. AUSTIN FLINT, JR.

New York, April 28, 1885.

To the Editor of the New York Medical Journal:

DEAR SIR: My professional reputation, such as it is, is sufficiently dear to me to make me desire to defend it, in a proper way and through proper channels, when it is publicly attacked, although I can scarcely imagine a provocation sufficient to induce me to enter into a personal controversy in the newspapers. I beg that you will do me the justice to publish the statement that I have to make, as well as the report from the "New York Herald," which has induced me to send you this communication.

At the last meeting of the New York Academy of Medicine I introduced resolutions instructing the Committee on Admissions to report to the Academy, for election as resident Fellows, no physician who could not consistently sign the by-laws of the Academy; and another resolution reaffirming the by-laws of the Academy as far as they referred to medical ethics. The simple facts with regard to this action in the Academy are as follows:

From the fact that its by-laws include the Code of Ethics of the American Medical Association, the Academy of Medicine is the only society in the State of New York which is entitled to representation in the American Medical Association, or in the regular medical societies of any of the other States. This is because the New York State Medical Society, which carries with it in this matter all the county societies, has adopted a code of ethics opposed to the code of the American Medical Association; which latter code is adopted by the medical societies of all the other States in the Union.

The fact that the president and first vice-president of the Academy, as well as other officers, actively and publicly advocate the State code, which is opposed to the by-laws of the Academy, excites alarm on the part of many Fellows of the Academy, and a fear that the standing of the Academy may, by the attitude of its prominent officers, be gravely compromised.

Animated by this feeling, a number of Fellows of the Academy, who are in favor of its by-laws as they now exist, and who include four of the five living ex-presidents, prepared a set of resolutions reaffirming the ethical portion of the by-laws, and I was selected to present these resolutions to the Academy at a regular stated meeting. We also notified those who were known to be in favor of the existing code of ethics of the Academy that resolutions would be introduced at the last stated meeting relative to the election of resident Fellows. Those acting in this matter conceived that it was not only their right, but their duty, in the existing condition of the Academy, to introduce these resolutions, and to ask those who were known to agree with them to be present.

The resolutions, which you have already published, were accordingly introduced by myself, and were carried by a vote of two to one. By recognized parliamentary procedure, which involved no abridgment of discussion, they were made as binding upon the Academy as possible.

During the entire discussion of the resolutions, I made no personal allusion, used no unparliamentary language, and conducted the part of the proceedings that had been assigned to me, as I hope, with courtesy and moderation. I used the single argument, if argument it can be called, that, in my opinion, a majority of the Fellows of the Academy desired to maintain its standard of medical ethics, so long as the code is not modified by the American Medical Association, as the only way of preserving the relations of fellowship of the Academy with the American Medical Association and the regular medical societies of other States.

This action on my part has subjected me to violent personal attacks in the newspapers, which attacks include the statement that I have "pulled down my venerable father from a pinnacle that was beautiful and lovely and dragged him in the mud."

I now ask you to reprint the inclosed, which is taken from the "New York Herald" of April 21st, in order that the profession may form an opinion as to the justifiability of the personalities therein contained. I trust that my professional brethren will credit me with the intention of acting in this matter according to my sense of right and duty, and with an honest endeavor to fight this battle temperately and impersonally, as well as with courage and firmness.

Yours very truly,

A. FLINT, JR.

*. The following, taken from the "New York Herald" for April 21st, is what Dr. Flint asks us to append to his letter:

"DOCTORS AT LOGGERHEADS.—LIBERALS AND ANTI-HOMOEOPATHS DISCUSSING THE CODE OF ETHICS.—TROUBLE IN THE ALLOPATHIC CAMP.—A SECRET MEETING OF THE LIBERALS AT DR. JACOBI'S RESIDENCE.

"Drs. Austin Flint, Jr., S. S. Purple, and J. W. Gouley are the recognized leaders of the anti-homoeopaths in this city, while Dr. C. R. Agnew and Dr. D. B. St. J. Roosa lead the liberal hosts. At the meeting of the Academy of Medicine Thursday evening the Flint party stole a march on the liberals by having adopted a set of resolutions the aim of which was to perpetuate the present Code of Ethics of the American Medical Association.

"DR. FORDYCE BARKER ASTONISHED.

"Never in my life was I so astonished and mortified as I was last night," said Dr. Fordyce Barker last evening, after he had sat a quiet listener to the proceedings of the secret meeting for nearly three hours. "Although I got notice during the afternoon that it was the intention of Dr. Austin Flint, Jr., to pack the meeting and throttle the Academy, I would not believe that it was possible for him to do it. But, for fear he would do it, I secured the presence of Dr. Weir, the first vice-president, so that I could resign and call him to the chair in case Dr. Flint undertook to carry out his plan, and he did carry out his scheme. It was a disgraceful, abominable trick, and only fit to be undertaken by a low ward politician. In doing this he pulled down his venerable father from a pinnacle that was beautiful and lovely and dragged him in the mud. I was greatly moved by what took place, but managed to preside, as I believe, with impartiality, till the meeting was over. When I got home I thanked God, for the first time in my life, that I have no voice. For if I had been a Demosthenes I would have left the presiding officer's post and answered the conspirators from the floor. As it is, I can only feel mortification and shame for the men—none of them very heavy-weights—who perpetrated this cowardly trick. For the rest of my life I can only treat Dr. Flint with required civility. He may think that he has won a great victory, but he will find out his mistake. And now I wish to announce that, although I offered my resignation as president of the Academy of Medicine last evening, I here withdraw it. I have five clear months between this and the next October meeting of the Academy, and by that time I think I will have been able to thwart the designs of the conspirators."

BELLEVUE HOSPITAL MEDICAL COLLEGE AND THE CODE QUESTION.

New York, April 25, 1885.

To the Editor of the New York Medical Journal:

SIR: The subjoined correspondence between the Faculty of the Bellevue Hospital Medical College and myself followed upon a proposition by the Faculty that I should recede from the position which I took at the recent meeting of the State Medical Society in opposition to the re-enactment of the code of ethics of the American Medical Association in this State.

[DR. HOWE TO DR. FLINT.]

"DR. AUSTIN FLINT, JR.,

"Secretary of the Faculty,

"Bellevue Hospital Col.

"DEAR SIR: Having been informed by Professor Joseph D. Bryant that, unless I could join with the rest of the Faculty in supporting the code of the American Medical Association, my resignation would be acceptable, I hereby tender my resignation as Professor of Clinical Surgery in Bellevue Hospital Medical College.

"Resp. yrs.,

"JOSEPH W. HOWE, M. D.,

"38 W. 24th St."

[DR. FLINT TO DR. HOWE.]

"BELLEVUE HOSPITAL MEDICAL COLLEGE,

"NEW YORK, April 28, 1883.

"PROF. JOS. W. HOWE.

"MY DEAR SIR: I am directed by the Executive Committee of the Bellevue Hospital Medical College to inform you that, at a meeting held last evening, your resignation as Clinical Professor of Surgery was accepted. I am also directed to express to you, in behalf of the Faculty, their warm appreciation of the valuable services you have rendered the college as a clinical teacher, and their regret that circumstances should exist which induce you to sever your connection with them. While they can not agree with you in opinion upon certain matters, your attitude certainly commands respect; and it is the hope of the Faculty that the kind feelings which have existed between you and them during the time of your connection with the institution may not be disturbed.

"Yours very truly,

"A. FLINT, JR.,

"Sec."

Yours truly,

JOSEPH W. HOWE.

Miscellany.

THE "NATION" ON THE CODE QUESTION.—In an article entitled "The Medical War," published in its issue of April 26th, the "Nation" says:

"The trouble between the 'regular' and the 'irregular' doctors over the Code of Ethics—in other words, over the propriety of allowing consultations with homœopaths—led to an exciting meeting of the New York Academy of Medicine on Thursday. The new code adopted by the State Medical Society allows such consultations; but there appears to be a question whether the action of that society is binding on the New York Academy, or whether this institution is not still governed by the old-fashioned ethics. Accordingly, resolutions were introduced on Thursday by Dr. Flint, and, after a stormy discussion, adopted, declaring that no physician known to be opposed to the old system should be eligible in future as a resident Fellow. The vote was fifty-eight to twenty-five, and among the minority were a number of physicians of the highest professional standing. The fact is, that, as all the proceedings of the various medical bodies during the past year show, the profession is divided in opinion as to the code; and this division of opinion is what strikes the layman in reading the accounts of the various meetings, rather than the success of one party or the other. Such a division means, of course, that instead of one code of ethics we shall probably now have two in use, in this State, at least; but it does not seem that they will differ in any point but one. The regulars insist on maintaining 'the dignity of the profession' by forbidding consultations with homœopaths, while the irregulars insist on considering the interests of the sick simply in all consultations.

"It is not difficult to foresee how the affair will end. The new code must eventually triumph, because all the influences of the times are on its side. Nothing that the irregulars ask for involves in the smallest degree any concession of the claims of homœopathy to be

considered a scientific method of treatment. Their amendment does not provide for the joint treatment of any case by an allopath and homœopath. It simply permits the allopath to give his opinion to any one who asks for it, and is willing to pay for it, without inquiring into his motives or character. It allows a regular physician to tell any sick person or his medical attendant what he thinks of the case, and to receive a fee for so doing. It binds him to no approval of the treatment previously pursued, for he may disapprove of it wholly. Those who ask for the opinion, in fact, indicate by their asking that they are doubtful about this treatment themselves, and think it not unlikely that he will disapprove of it. Their asking for it when the treatment has been homœopathic is, in fact, a concession to allopathy; and the most singular thing to us in the present discussion is that the regulars should not see it in this light, and encourage their members to go into consultation with homœopaths whenever the latter seek it. There is probably no other calling in which it would be considered improper for an orthodox practitioner to tell what he thought about his condition to a heretic or infidel who asked what he should do to be saved.

"Physicians, as well as all other scientific men in our time, must come to regard themselves, not as bands of tradesmen, interested in keeping up the prices of their goods and discouraging competition, but as reservoirs of the best knowledge of the day, from which everybody is at liberty to draw. If homœopaths were absolute and recognized impostors, it would not constitute an excuse for refusing to tell a patient who had fallen into their hands what he should do to get well. On the contrary, the worse a regular thinks of homœopaths the more eager he ought to be to get access to the unfortunates who are under their treatment. If his advice is taken, and the patient gets well under it, the result is a victory for orthodox medicine and a defeat for what he considers quackery. If it is not taken, the patient is no worse off than he was, and the regular physician is better off by the amount of his fee. The quarrel, in fact, reminds one of the Irish priest who complained much of the low moral condition of his flock, whose evil ways he was unable to restrain even by occasional horsewhipping. Being asked whether he had ever tried the Gospel on them, he answered, indignantly, that 'he was not going to waste good Gospel on the likes of 'em.' In fact, the notion that there are classes of people so low and wicked that they are not even entitled to religious teaching, is hardly more ridiculous than the notion that there may be sick persons so deluded and gone astray that it would not be right for an orthodox doctor to tell them, even for a fee, what is the matter with them, and what will cure them—that homœopathy so degrades and dehumanizes them that a good allopath ought not to advise them to give it up."

TO THE MEDICAL PROFESSION OF THE STATE OF NEW YORK.—We are asked to publish the following:

We, the undersigned, ex-presidents of the New York Academy of Medicine, desire to record our approval of the action taken by the Academy at the stated meeting of April 19, 1883, reaffirming the ethical clause of its by-laws and our indorsement of the course pursued, by request of the council of the central organization of the New York State Medical Association, as presented at this meeting by Austin Flint, Jr.

WILLARD PARKER, M. D., President N. Y. Acad. Med. 1856.

JAMES ANDERSON, M. D., President N. Y. Acad. Med. 1861 to 1867.

AUSTIN FLINT, M. D., President N. Y. Acad. Med. 1873 to 1875.

SAMUEL S. PERPLE, M. D., President N. Y. Acad. Med. 1875 to 1879.
NEW YORK, April 20, 1883.

A COMMENTARY ON THE CODE CONTROVERSY.—The New York correspondent of the "Chicago Medical Journal and Examiner" writes as follows:

"I have no doubt that the medical profession is somewhat tired of the subject of medical ethics. But the discussion continues, and recently the 'New York Medical Journal' has opened its columns to a series of articles *pro* and *con*. Perhaps I may be excused, sometimes, for saying something of the matter now. The disinterested observer who visits New York would have to question many physicians before he found one who felt any particular interest in the present ethical fight. At the best attended meeting, called to vote upon the subject,

only about one fourth of the members of the county society, and perhaps one tenth of the regular profession of the city, was present. The general feeling is, that the real importance of the question has been exaggerated by outside agencies for an advertising purpose; and that medical practice here, as everywhere, goes on with very little reference to disciplinary codes. This view is strengthened by the fact that no case of discipline for consulting with irregulars has occurred in fifteen years in this city, or, I believe, in the State. It is somewhat curious that, before the new code, instances of sinful consultation by certain eminent physicians were well known to occur, and that some, to whom the practice was most ascribed, are now vigorously championing the old code.

"It is a mistake to think that there is any especial antagonism among the physicians of the city. I do not think that many favor the present code as a whole, but only the non-restrictive clause in it. The majority prefer, I should say, the declaratory resolutions, or Gentleman's code. Many others would like the old code minus the restriction clause, and a little refurbished in other respects.

"It is idle to expect that New York will ever return to the old code in its entirety, however. It would require a two thirds vote to do it, and at the last meeting of the State society, despite most laborious canvassing, there was not even a majority. The meeting was a full one, and each side did its best to bring out all its friends. The battle was fairly fought, with no parliamentary tricks or political manipulation. The vote represented the general feeling in the State. This is shown by the canvass made by Dr. Smith, the secretary of the society. Among nearly seven hundred answers to his query as to which side the individuals took upon the matter of the code, there were about three hundred and forty in favor and not quite three hundred against the present code. About one third of the profession of the State live in New York, and less than one third of the answers came from this city, the 'ayes' and 'nays' being about eighty to one hundred and twenty, as I remember the figures. So that the returns represent the feeling in the country, as well as city.

"The statement is made that of the fifty-nine county societies only six have taken action in favor of the present code, while thirty-six have taken action against it. It should be borne in mind, however, that the six include New York County, Albany County, and Kings County, and that their representation is forty-seven out of the total of one hundred and twenty-three county delegates. Assuming that the seventeen counties which took no action had but one delegate, there would still be considerably over one half of the county representation which took no action against the code. I have assumed that Kings County is favorable to non-restriction, because I understand and believe that the vote rescinding instructions to delegates really represented the feeling of the majority of Brooklyn practitioners.

"Perhaps one reason why the State of New York sustained its last year's action is to be found in the character of the criticisms made upon it. Here are some examples: 'It disturbed "a custom approved and sanctified by wisdom and experience of ages"'. 'A disgraceful act.' 'In the interest of specialists.' 'It (the code) does not exclude the licensed cancer quack, midwife, or chiropodist.' 'Fifty doctors, reckless of honor, and greedy for gold, undertook to sell out the profession.' 'A complete surrender to homoeopathy.' 'It (the code) asserts the propriety of consulting with homoeopaths.' 'Most unwise, ill-timed, and injurious, . . . untenable in every respect, and not sustained by the action of any other respectable body in Europe or America.' 'An unwise and useless code—a code which sacrifices the self-respect and honor of the members of a once honorable profession in order to pander to the interests of a few specialists.' 'Hurried through by a small majority.' 'A significant fact that the new code agitation was entirely inaugurated by specialists, and that every man who has taken at all an active part in securing its adoption and preventing its repeal is a specialist.'

"It has been keenly felt that these charges are, every one of them, untrue and unjust. Their constant iteration has, no doubt, made converts to the other side. For this reason, also, many in the city who did not entirely approve of the new code, felt gratified, after all, that it was sustained. The charge against the specialists is made each time with as much triumph as if the authors had achieved an intellectual

victory, and satisfactorily solved the whole problem of ethics. But I think all candid men will agree that this is a side issue; that the question is really as to the right and advisability of allowing individual freedom in professional conduct, just as is allowed to members of all other professions and pursuits. At any rate, in the State society, it was not a question between specialists and general practitioners, for among the hundred and five votes for the new code I can count only sixteen specialists. In this city the proportion of specialists among the anti-code men is relatively considerable. The Southern and Western gentlemen who say such severe things against the honesty of New York physicians are probably ignorant of the methods in which specialists here do their work. This is chiefly done in the office, and the general practitioner does not bring his patients, but sends them. The patient is examined and prescribed for independently of his own physician.

"I do not write to defend our specialists, however, who can, no doubt, take care of themselves; but only for fair treatment toward them and toward the profession of New York. It seems to me that there is no call for so much violent feeling and vituperative language. The profession is not going to be destroyed or disintegrated, as has been intimated. I do not think that we are victims of moral decay. I find it perfectly safe to mingle freely with my neighbors. The view in this city, I think, is, that, by removing a restriction that had been a dead letter, we have placed ourselves in a better light before the world; have removed an affront and a stimulus to homoeopathic progress, and have only set aside a technical morality which infringed on the individual's rights without elevating him in return. We believe that the true work for professional elevation lies in securing a higher educational standard, better-trained minds, a more scientific spirit, and a greater technical skill in our midst. We believe that this work can be better done without the embarrassment and reproach caused by the restrictive code. We believe that skilled and learned physicians, obedient to the laws of God and the dictates of common morality, are what the profession needs."

THE PHILADELPHIA HOSPITAL FOR SKIN DISEASES.—The Board of Managers of the Hospital for Skin Diseases, of Philadelphia, announce that they have recently added to their facilities a complete system of baths for the general and specific treatment of this class of affections. Under this head are comprised the Turkish, Russian, vapor, medicated, and electric baths, for the giving of which the latest and most approved apparatus has been obtained at considerable cost. The subject of balneology, as connected with skin diseases, is receiving much attention from specialists, and the physician in charge of the hospital is giving it the consideration that the importance of the subject demands. Peculiar advantages are thus afforded physicians and advanced students who wish to obtain a knowledge of this branch of therapeutics by visiting the hospital and consulting with the attending physician. Free clinics are given at the hospital daily, at 11.30 A. M., by the physician in charge, Dr. John V. Shoemaker, where a great variety of diseases can be seen. The large variety of cases presented enables those who attend the clinics to gain in one or two courses a practical knowledge not obtainable in private practice. The course is made more comprehensive by didactic lectures which are delivered at the hospital on Mondays and Fridays, at 11 A. M. The hospital has accommodations for twenty-five patients in the wards and private rooms. The prices in the former range from four to seven dollars a week; and in the latter from ten to thirty dollars. The best of food and attendance are furnished, and everything is done to render the patients cheerful and contented during their stay in the institution. Physicians and advanced medical students are always welcome, either as visitors or for the purpose of attending the free clinics. The superintendent, Mr. F. C. Waterman, will be in his office at the hospital every day from 11.30 A. M. to 2 P. M., to receive visitors or to transact business.

THE DECLINE OF HOMOEOPATHY IN ENGLAND.—Dr. W. Wilberforce Smith writes as follows to the "Lancet": "The 'Homoeopathic Directory,' published by Leath and Ross in 1862, indicates that the system was in its infancy in this country more than half a century ago, having been represented in 1830 by a single practitioner. In its twenty-fourth year (1853), according to the same authority, it had so

grown as to be represented by 213 members. In 1862, after nine more years, the same 'Directory' shows 218 qualified practitioners; that is, a small increase of five. A few years later the numbers had increased, according to the 'Homœopathic Directory,' published by Turner, of Fleet Street, in 1866 to 227, in 1867 to 246, in 1868 to 258, in 1869 to 268, and in 1870 to 273, representing a total increase of 55 qualified practitioners in eight years. In the subsequent and most recent decade all substantial increase from the ranks of the profession soon ceases. In 1871 there were 278 practitioners; in 1872, 279; 1873, 284; 1874, 279. Then, according to the 'Directory' of the Homœopathic Publishing Company, Finsbury Circus, in 1875 there were 269 qualified practitioners; 1877, 249; 1878, 268; 1879, 275; 1880, 275. Thus there was an increase in the decade, counting from 1870, of only two practitioners. Considering the increase of population and the increase in the numbers of the profession generally, the schism had evidently been losing ground during this decade, notwithstanding the establishment of a London School of Homœopathy, founded with the express object of promoting the system among members of the profession, and notwithstanding also, as I have reason to know, the promise held out to students of a lucrative speciality. In 1881 the number of practitioners willing to enter themselves in the 'Homœopathic Directory' had actually diminished to 267, and in 1883, as you have informed your readers, the whole number amounted to only 260—a serious fact for a system which is nothing if not belligerent and in creasing.

"For myself, I rejoice that there are signs of greater toleration among the profession, because homœopathy, like every important sect in medical history, has legacies of truth to leave behind it, and numbers in its ranks many men of truth and honesty. Equally do I rejoice that, as a system holding out its flag and sounding its trumpet to attract the attention of the public, its inevitable decay is in sure progress."

SUBSTITUTES FOR MOTHER'S MILK.—In the March number of the 'American Journal of Obstetrics' Dr. S. B. Sherry, of Delafield, Wis., writes: "I have tried the following mixture as a substitute for mother's milk in a number of cases, and it has always proved very successful. . . . I direct the nurse to add a pint of barley-water to an ounce of pearl barley, and allow it to cool, and then strain it. One third of a pint of this barley-water, and two thirds of a pint of fresh, undiluted cow's milk, are mixed, and sweetened with a teaspoonful of milk-sugar. It is very important that common sugar be not used. We have here a mixture very closely resembling human milk in color, taste, and consistence, and I have learned to rely upon it with great confidence."

The 'Lancet' quotes the 'Physician and Surgeon' to the effect that Professor Frankland's method of preparation of artificial human milk is as follows: "Let one third of a pint of fresh cow's milk stand twelve hours, then remove the cream, and add to it two thirds of a pint of new milk as fresh from the cow as possible. To that one third of a pint of blue (or skim) milk left after taking away the cream, add a piece of rennet (about one square inch in size), which, after it has served its purpose, can be taken out and used daily for a month or two, and allow the vessel holding the skim milk to be placed in warm water, and there remain for from five to fifteen minutes, until curdling is effected. Break up the curd repeatedly, and carefully separate the whole of the whey, which should then be rapidly heated to boiling in a small tin pan, placed over a spirit- or gas-lamp; during this heating a further quantity of casein (technically termed 'fleecings') separates, and so straining after this, through fine muslin, is then required. Now dissolve one hundred and ten grains of powdered milk-sugar in hot whey, and mix it with two thirds of a pint of new milk as before prepared with extra cream. This gives one pint of artificial human milk, which should be used within twelve hours of its preparation. All vessels and apparatus concerned in the manufacture must be kept scrupulously clean."

SUBCUTANEOUS INJECTION OF ETHER.—M. Hayem, Professor at the Paris Faculty of Medicine, in a communication recently made to the Academy of Medicine on the utility of hypodermic injections of ether when death from hemorrhage is imminent, asserts that injections of ether practiced on a dog which had lost so much blood as to have

tetanic convulsions, and to be on the point of death, were followed by no perceptible results. In a similar case, transfusion of blood containing all its constituent parts was followed by, as it were, a veritable resurrection. When a sufficient quantity of blood (one nineteenth of the weight of the body) is removed from the animal, to place it just on the boundary between imminent death and possible survival, the result of subcutaneous injection of ether is equally negative. In the same circumstances, not only is transfusion of blood successful, but even, in some cases, recovery ensues, when the blood still remaining in the organism of the animal is diluted with serum taken from another animal of the same species. M. Hayem is of opinion that these facts indicate that it is a mistake to affirm that transfusion is a useless operation, and that the stimulation produced by hypodermic injections of ether can be substituted for it. Stimulation by ether, he remarks, increases the force of the cardiac contractions, and quickens the heart-beats in a remarkable manner, but it does not increase blood-pressure, nor raise the temperature in the rectum.—*British Medical Journal*.

THE SANITARY INSTITUTE OF GREAT BRITAIN.—The Autumnal Congress of the Sanitary Institute of Great Britain will be held this year in Glasgow, from September 26th to 29th. The exhibition of sanitary apparatus and appliances in connection with the Congress will remain open until October 20th.—*Med. Times and Gaz.*

THE SALICYLATES AND HEMORRHAGES IN ENTERIC FEVER.—Dr. James Fergusson, of Perth, writes: "At the time when salicylic acid and its compounds are receiving so much attention, may the following facts be regarded as at least worthy of statement? Last year, while resident in the infirmary here, I had an opportunity of testing the efficacy of certain drugs as antipyretics in enteric fever. These agents were used successively, each over a group of cases, and included the salicylate of soda. The latter had not been long in use when an increased frequency of hemorrhages from the bowel raised the question, Could the salicylate be favoring the production of that complication of the malady? Whether it were or not, the suspicion aroused dictated the withdrawal of the salt from use in cases of typhoid. Shortly afterward, I noticed that a foreign observer had reported the salicylate of bismuth, and, I think, also salicylic acid (though of the latter I can not be certain, as I am not able now to find the report in question), to cause intestinal and nasal hemorrhages. The subject would not have been revived by me at present but for the recent experience of my successor in the resident's office of the above-mentioned institution, D. H. McLean Wilson, who joins me in placing the facts before the public. Dr. Wilson, in having recourse to the soda-salt in typhoid, found the same striking frequency of hemorrhages to follow closely. His employment of the agent differed from mine, in that he administered small doses of ten to fifteen grains frequently over the twenty-four hours, while I gave half-drachm or drachm doses at longer intervals apart. In the other respect, however, our experiences have been so similar as to warrant the facts being brought under notice, so that the important practical question involved may, if possible, be decided by the evidence of a number of observers."—*British Medical Journal*.

AN INTERNATIONAL CONGRESS OF COLONIAL PHYSICIANS.—An international congress is to be held in Amsterdam in September, at which medical matters are to be considered with special reference to the needs of colonies. The subject of quarantine will be discussed by Dr. F. de Chaumont, Professor of Hygiene at Netley; Dr. Van Leent of Amsterdam; and Professor R. Cervera, of Madrid. The special education of colonial physicians will be treated of by Colonel Becking, of Utrecht, formerly chief of the Dutch East Indian Medical Service. Hygiene in relation to unwholesome occupations in colonies will fall to Dr. Da Sylva Amado, Professor of Hygiene in the Medical School of Lisbon, and Dr. Van Overbeek de Meyer, Professor of Hygiene at the University of Utrecht. The modifications which certain diseases, particularly the infectious diseases, undergo under the influence of tropical climates will be spoken of by Dr. Walther, a medical inspector in the French navy, and by Dr. Norman Chevers, of London, formerly Professor of Medicine in Calcutta. Phthisis in colonies and in tropical climates will be reported on by Dr. B. Carsten, adjunct-inspector in

the medical service of the Hague. Sir Joseph Fayrer, Surgeon-General of India, Dr. Joseph Ewart, Deputy Surgeon-General, and Dr. Le Roy de Méricourt, Physician-in-Chief of the French navy, will remark upon the treatment of exotic and tropical diseases in temperate climates.

THE ILLINOIS MEDICAL LAW.—In a recent report by the secretary of the Illinois State Board of Health, Dr. J. H. Rauch, that officers say: "Among the certificates issued during the past month a considerable number were to practitioners exempt from the Medical-Practice Act, by reason of length of practice in the State, but who have recently graduated from reputable medical colleges; and also to others holding certificates based upon examinations, and who have pursued the same course. It is gratifying to be able to record this result of the recommendation of the board, whose policy it has uniformly been to urge non-graduate candidates for its certificates to complete the regular curriculum of study, and obtain the diploma of a college in good standing. As nearly as can be ascertained, there are now only about 650 non-graduates left in the State, as compared with about 3,800 at the time when the law went into effect."

THE FACULTY OF THE POST-GRADUATE MEDICAL SCHOOL.—Dr. Edward L. Partridge has been appointed professor of obstetrics, and Dr. Charles S. Ward professor of diseases of women in conjunction with the present incumbent, Dr. Dawson.

THE ILLINOIS STATE MEDICAL SOCIETY.—The annual meeting of the society will be held at Peoria, beginning May 15th.

THE ARKANSAS STATE MEDICAL SOCIETY.—We are indebted to the secretary, Dr. L. P. Gibson, for information in regard to the eighth annual meeting of the State Medical Society of Arkansas, to be held at Little Rock on Wednesday and Thursday, the 30th and 31st instant. The following committees are to report: On Medical Education—T. W. Hurley, Chairman; W. B. Welch, W. A. C. Sayle, W. H. Hawkins, W. H. Hardison, D. C. Ewing, D. H. Dungan. On Practice of Medicine—J. A. Dibrell, Sr., Chairman; D. H. Dungan, T. D. Nichols, Z. Orto, G. W. Hudson, A. N. Carrigan, G. M. D. Cantrell, P. H. West, J. F. Simmons. On Surgery—J. A. Dibrell, Jr., Chairman; J. R. Dale, C. L. Kirksey, William B. Lawrence, J. E. Bennett, J. M. Keller, W. B. Welch. On Gynecology—Edward Cross, Chairman; R. N. Ross, W. H. Heard, J. F. Blackburn, D. S. Williams. On Medical Legislation—R. G. Jennings, Chairman; G. B. Malone, A. A. Horner, C. Watkins, P. Van Patten, W. W. Hipolite, A. B. Loving. On Neurology—A. N. Carrigan, Chairman; R. B. Gladden, J. T. Jelks, J. F. Blackburn, G. S. Brown, E. H. Alexander, R. C. Wallis. Board of Visitors to the Medical Department of the Arkansas Industrial University—Isaac Folsom, Chairman; J. E. Bennett, W. W. Hipolite, W. H. Hawkins, Z. Orto. Committee on State Medicine—Z. Orto, Chairman.

THE WEST VIRGINIA STATE MEDICAL SOCIETY.—The Medical Society of the State of West Virginia will hold its sixteenth annual session in the Court House at Grafton, commencing at two o'clock, p. m., Wednesday, May 16th.

A NEW SOCIETY IN MEXICO.—Under the title of the "*Sociedad Médico-mutualista Zacatecana*," a society has been formed at Zacatecas, for the purpose, as stated in a circular recently sent us, of promoting instruction, morality, and reciprocal aid among its members. Dr. Luis G. Gonzalez is the president, and Dr. Eufemio J. Gutierrez the chief secretary.

SMALL-POX IN FLORIDA.—We have information to the effect that small-pox is very prevalent in Jacksonville, chiefly among the negroes, and that many points on the St. John's River are quarantined in consequence of the prevalence of the disease.

SMALL-POX IN MERCER COUNTY, WEST VIRGINIA.—Under date of April 30th, Dr. James E. Reeves, Secretary of the Virginia State Board of Health, writes from Wheeling as follows: "A telegram was received at this office yesterday announcing the discovery of twenty cases of small-pox in Mercer County, West Virginia. The State Board of Health has been appealed to for help. The greatest excitement prevails among the people of that county. Complete instructions have been sent by telegraph how to compass the situation."

THE INFECTIOUS DISEASES OF DOMESTIC ANIMALS.—We learn that the Legislature of the State of New York has appropriated \$5,000 to be used, under the direction of the State Board of Health, we presume, in the prevention of pestilential diseases among our domestic animals.

THE UNITED STATES MEDICAL COLLEGE.—The following resolution was adopted at a recent meeting of the Illinois State Board of Health:

Resolved, That, under the recent decision of the Supreme Court of the State of New York declaring the charter of the United States Medical College of New York null and void, this board can no longer legally recognize the diplomas of that institution.

A PORTRAIT OF MR. ERNEST HART.—At a recent assemblage of more than five hundred persons, mostly physicians, held at Grosvenor House, London, Mrs. Hart was presented with a portrait of her husband, the distinguished editor of the "*British Medical Journal*," "in recognition," as the invitations stated, "of his many and valued services rendered to the profession at large, and especially to the Army and Navy Medical Services, and the influence which, during twenty-five years, he has exercised on sanitary and social progress, the advancement of the welfare of the sick poor, and the cause of public health."

DEATH OF DR. H. B. WILBUR, OF SYRACUSE.—Dr. H. B. Wilbur, Superintendent and Physician of the New York State Asylum for Idiots at Syracuse, and a member of the State Board of Charities, died suddenly on the morning of the 1st instant. Dr. Wilbur was graduated, in 1843, from Berkshire Medical College.

DEATH OF DR. JAMES PALFREY, OF LONDON.—The "*British Medical Journal*" announces the death of Dr. Palfrey, for many years an obstetric physician to the London Hospital.

DEATH OF M. KRISHABER.—We learn from the "*Union médicale*" that Dr. Krishaber, the eminent laryngologist of Paris, died of typhoid fever on the 10th of April, about a month after the death of his wife.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from April 21, 1883, to April 28, 1883.*—CLEARY, PETER J. A., Major and Surgeon. So much of Par. 10, S. O. 273, November 23, 1882, from this office, as directs him (then captain and assistant surgeon) to report in person to the commanding general Department of Dakota, is revoked, and, upon the expiration of his present sick leave of absence, to report in person for assignment to duty in the Department of the Missouri. S. O. 95, A. G. O., April 25, 1883. — HOPKINS, WILLIAM E., First Lieutenant and Assistant Surgeon. Now on leave of absence in New York city, to be relieved from duty in the Department of the East, and assigned to duty in the Department of Arizona. Par. 7, S. O. 95, A. G. O., April 25, 1883.

NAVAL INTELLIGENCE.—*List of Changes in the Medical Corps of the Navy for the week ending April 28, 1883.*—Surgeon J. B. Parke, ordered to the Torpedo Station, Newport, R. I., vice Surgeon William J. Simon, detached and waiting orders. — Passed Assistant Surgeon M. H. Simon, detached from the Naval Hospital, Chelsea, Mass., and ordered to the Naval Hospital, Yokohama, Japan, vice Passed Assistant Surgeon C. Biddle, detached and ordered to the Richmond. — Passed Assistant Surgeon A. A. Austin, from the Richmond and ordered home. — Assistant Surgeon J. H. Bryan, ordered to report May 1st for examination for promotion.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, May 7th:* Medico Chirurgical Society of German Physicians; Morrisania Medical Society (private). *Tuesday, May 8th:* East River Medical Association (private); Jersey City Pathological Society; Newark Medical Association (private); New York Academy of Medicine, Section in Surgery; New York Surgical Society. *Wednesday, May 9th:* Medical Society of the State of Pennsylvania (Norristown); New York Pathological Society. *Thursday, May 10th:* Brooklyn Pathological Society; Medical Association of the Eastern District of Brooklyn; Public Health Association of New York. *Friday, May 11th:* Yorkville Medical Association (private). *Saturday, May 12th:* New York Medical and Surgical Society (private).

Lectures and Addresses.

LECTURES ON HUMAN AUTOMATISM.

DELIVERED AT THE LOWELL INSTITUTE, BOSTON.

By WILLIAM B. CARPENTER, M.D., LL.D., F.R.S., Etc.

(Concluded from page 481.)

The next point to which I have now to advert is the remarkable influence of the *direction of the attention* in the selection of those sensory impressions which we have any purpose or desire to exalt. You know very well the difference between *listening*, for example, and merely hearing sounds; between *looking at* an object fixedly and the mere seeing it. The one is an active state of the mind, involving the purposive direction of the attention, while the other is its passive reciprocity of whatever comes within the scope of the senses. And it is in this direction of the attention that, I think, we have the *rationale* of a great number of phenomena which, at first sight, seem very difficult of explanation. We every now and then meet with cases in which there is an extraordinary receptivity for some particular kind of sensory impressions, others being as entirely disregarded as if the organs of sense were closed to them.

It is commonly supposed that the exaltation of one sense, which occurs (as in the case of Laura Bridgman) when other senses are wanting, is due to an improvement in its organ. But I shall be able, I think, to show you that it is chiefly, if not solely, attributable to the complete restriction of the attention upon the one kind of sense-perception which remains open. This you well know, in Laura Bridgman's case, to be the touch, as to which she has not only an extraordinary acuteness of discrimination, but an extraordinary recollection of differences so slight as not to be even perceptible to ordinary people. Thus, she can not only at once recognize, by a slight touch of the hand, all the persons with whom she is intimate, but, when she has once held the hand of a new visitor for a short time, she can recognize that visitor again after an interval of several months, just as any one of us would do by our sight. It was a visit which a brother of mine paid her, some thirty-five years ago, that put me in possession of that fact. He brought an introduction to her; and, his relationship to the writer of that introduction having been explained to her, she took one of his hands into her own, so as to take in from it the impression of his personality which the seeing person derives from looking at the face. He called on her two or three times, I believe, during his first visit to Boston, and had conversations with her through her interpreter, and afterward traveled for about twelve months in different parts of the United States. On coming back to Boston, before leaving for England, he paid her another visit, and she immediately recognized him, after that interval, when she took his hand into hers.

Now, I am far from denying that the habitual and exclusive use of one sense-organ, and of the parts of the cen-

tral apparatus with which it is connected, may so improve their structural adaptiveness as to make them more efficient instruments, on the one hand, for conveying sense-impressions to the consciousness, and, on the other, for enabling the mind to profit by them. But what I have witnessed, over and over again, in cases of natural and induced somnambulism, has satisfied me that a scarcely inferior acuteness of sense-perception may be shown by persons who, having full possession of their senses during their ordinary lives, have undergone no such training; and that the main condition of it lies in the exclusive concentration of the attention upon some one particular kind of impressions, such exaltation not being confined to the touch, but being equally shown in the guidance of movements by the muscular sense, and in the discrimination of objects by the smell. Of this I shall give you two remarkable instances, the first of which I did not myself witness, but which was carefully observed by my late brother, Dr. P. P. Carpenter, while the second occurred within my own knowledge. The subject of the first case was a young gentleman, the son of an eminent solicitor of Manchester, occupying a high social position; and he was then recovering from a long and severe attack of rheumatism, affecting almost every one of his joints. For a reason I shall presently mention, he was placed under the care of Mr. Braid, of Manchester, whose "hypnotic" experiments, performed thirty years ago, are now coming to be generally recognized as important. I may say that I did my best at that time to bring them into public recognition; and they are now being taken up by scientific inquirers in Germany and France, and, I believe, in this country also, who will very likely add considerably to our knowledge of the curious state to which Mr. Braid's inquiries first drew attention. The young gentleman of whom I have spoken was crippled by the rheumatic stiffness of his joints; and any attempt to bring them into use by passive exercise was attended with so much pain that it was suggested that Mr. Braid should bring him, if possible, into a state of hypnotic insensibility, during which his limbs might be put in movement in various ways. After two or three exercises of this kind, he began to talk in his sleep; and it was soon found that, like many natural somnambulists, he could carry on a conversation. Though I believe that his eyes were open, it was quite clear that he did not see anything; for his head might be completely inclosed in an opaque covering, or a book might be held between his eyes and the writing which he could be prompted to execute, and he would take no notice whatever, but go on just as he did before. Now, if he was directed to write from dictation, he would take a slate or a piece of paper and pencil, and write down, with great regularity, anything that was read to him, shaping his letters very well, and keeping equal distances between the lines. But it was specially remarkable that he would afterward go back and dot his *i*'s and cross his *l*'s just as correctly as if he could see them, provided that the paper remained in the same position. But, if the position of the paper had been changed without his knowledge, he would put these dots and lines where they should have been if the paper had remained where it was.

If, however, he was made aware that the paper had been moved, he would take a new departure from its upper left-hand corner, and then would go on and dot his *i*'s and cross his *t*'s in the right places. In one instance, when he had been writing a German exercise, he thus put the diæresis over a German vowel, to the great astonishment of his German master, who was present. Now, in all this he must have been guided by the muscular sense alone; and it must be obvious to you that only by an extraordinary exaltation of this sense could he have done what I have been describing. But the circumstances of the case seem to me to leave no doubt that this temporary exaltation must have been entirely due to the intensity with which the youth's attention was concentrated upon what he was about, to the complete exclusion of every distracting impression. It was further found that his sense of smell was remarkably exalted in the hypnotic condition; and, a number of his father's friends having been brought together to see some of Mr. Braid's experiments, he was able, among seventy persons, to pick out unhesitatingly the owner of a glove which had been put into his hands, walking about among them snuffing like a dog. (The other glove had, of course, been put away, so that he had no guidance in his selection.)

I myself witnessed a case of the same exaltation in a young factory-girl, who was one of the subjects on whom Mr. Braid was at that time experimenting. Before entering his room, I took off a ring which I wore and gave it to Mr. Braid, to place in the hands of any of his subjects whom he might regard as most likely to discover it. There were not many persons in the room, perhaps eight or ten, but she at once assigned the ring to me. I had never seen her before I entered the room, and can not think of anything else than the temporary exaltation of her sense of smell that could have led her unhesitatingly to assign the ring to me rather than to any one else.

You see that in these cases there could have been no such habitually specialized use of the particular sense as would be required to produce such a structural change in its physiological apparatus as we may imagine to have occurred in a case like Laura Bridgman's. And I regard these and similar phenomena as affording proof of what the concentration of our attention may do in exalting the sensory impression made upon our consciousness, the same *neurosis* producing *psychoses* of very different intensities, according to our mental state on each occasion.

I may mention, as further illustration of the necessity of the *exclusive* concentration required for such highly specialized forms of sense-perception, that I have been assured by the Master of a deaf and dumb school, in which "lip-reading" is taught, that he considers it useless to endeavor to train to this interpretation of the movements of speech any one who is only partially deaf, as the distraction of the attention by the effort to *hear* what is spoken prevents that concentration of it on the face of the speaker which is requisite for the *visual* recognition of the words he utters. You must all be familiar with cases of the same kind, though differing in degree, which show how much our mental receptivity of any particular sensation or class of sensations depends upon the attention which we give to it;

and my next point is the power we possess of *determinately selecting*, between two or more concurrent sensory impressions, what we shall allow to enter our minds, so as to become the basis of higher mental operations, and what we shall more or less completely exclude. I am particularly desirous of impressing this point upon you, because in the two remaining lectures I shall have frequent occasion to advert to it.

I have again to refer you, by way of illustration, to a familiar experience—the way in which we can distract our attention from one class of sensory impressions by determinately attending to another, the intensification of the latter being accompanied by a corresponding abatement in the former. And this is equally true of the impressions made on our sensorium by external objects, and of those which arise from our purely subjective thoughts and feelings. Not only can we select between two kinds of impressions received (it may be) through different senses, or between two different trains of thought, but we can select between a train of thought and a series of sensory impressions. And the precise analogy between these three cases appears to me to afford a strong argument in favor of the view I have several times brought before you of the unity of the sensorium—the central organ which receives on its outer side impressions from the nerves of the external senses, and translates these into consciousness, receiving, also, from its inner side the impressions of cerebral change brought to it by the "nerves of the internal senses," and translating these, also, into states of consciousness. The selection between two different sets of sensory impressions, so that one is received while another is shut out, is what every microscopist does who has trained himself, when looking through the microscope with one eye, to keep the other eye open—a great saving of fatigue. Some persons never acquire this power, but I never myself have had any difficulty in it. I become perfectly insensible to impressions made on my left eye when I am using my right in looking through the lens of a single microscope, or the single body of a compound microscope. Some persons find it necessary to put a screen of some kind before the left eye, in order to allow it to be kept open (which, when microscopic observation is continued for some hours, is an absolute necessity for the avoidance of disagreeable and distracting muscular strain) without receiving visual impressions from objects within its range, which would interfere with the microscopic image formed by the right eye. But I scarcely ever find the need of this; and I believe that most observers who have worked much with a single eye would say the same. If a very bright object lies in the field of the left eye, its image may force itself on one's recognition; but objects which do not thus attract notice come by habit to be so completely unregarded that we may truly say that they are *not seen* by the mental eye, though their pictures are formed on that of the body, and the impressions of them are transmitted to the sensorium, just as in the case of the somnambulist.

There are cases, again, which I doubt not are very familiar to you, in which we can withdraw ourselves, as it were, from even severe physical pain by determinately fix-

ing our attention upon something else—either external objects or internal trains of thought. A very admirable example of that kind was presented not long since by a well-known physician of this city, Dr. Edward H. Clarke, with whose case I have become acquainted through my friend Dr. Oliver Wendell Holmes, who wrote a charming little notice of him affixed to the work on "Visions," which has been published since his death. The fatal malady from which he suffered during the latter months of his life produced the most agonizing pain; and yet he could determinately withdraw his consciousness (so to speak) from that pain by fixing it upon another object, that object being the working out of his own neutral train of thought in the composition of this book.* This is well known to have been the case, also, with regard to Sir Walter Scott, who, during a very severe and painful illness, dictated the "Bride of Lammermoor." And the most remarkable fact about its composition was that, after his recovery, he entirely forgot all that he had done, the book, on its publication, coming to him as an entirely new work, with which he had had nothing whatever to do. He only remembered the general outline of the story upon which he had composed his novel; this he had heard in early life, and it remained with him; but of the working-up of this story into the novel, while he lay on his sofa contending with paroxysms of agony, he had no recollection. Thus, in the case of Walter Scott, as in that of Dr. E. H. Clarke, we see the effect of determined fixation of the attention upon a train of ideas in mastering physical pain. And I shall give you another most remarkable example of the same thing in the case of Robert Hall, one of the most celebrated preachers of my early years, of whom I suppose most of you have heard. He used to go into the pulpit suffering the most agonizing pain, which was found, after his death, to have resulted from a large calculus in his kidney, with projecting points, the terrible suffering produced by which every medical man will at once appreciate; and was obliged habitually to take some of the largest doses of opium that were ever administered in order to keep this under at all. But from the moment he began his extempore sermon (the introductory service having been performed by his colleague) he seemed utterly unconscious of it. During the later portion of his life, which was passed in Bristol, I was often his hearer, and, like every one else, was most deeply interested in his discourses, while at times quite carried away by the torrent of his eloquence. I was assured by eye-witnesses that when he went down into the vestry he would sometimes roll on the floor in agony, though during his pulpit address he had ceased altogether to feel pain.

Now, some physicians, not physiologists, tell us that he must have felt the pain, but did not remember it. But he can not be said to have *felt* it while he was utterly unconscious of it, his mind being exclusively engaged in develop-

ing and uttering his train of religious thought. He could keep the part of the sensorium in connection with his cerebrum in a state of activity so exalted that it would withdraw the activity from the other part in connection with the nerves of sense—a state which I do not think any physiologist need now have any great difficulty in accounting for, in the light which the "vaso-motor" physiology of the present day throws upon differences in the amount of blood supplied to the two parts. For the larger supply of oxygenated blood and the greater activity of physical change in what may be designated as the upper or cerebral aspect of the sensorium would simply diminish the supply of blood, and reduce the physical activity of the lower portion—that in direct connection with the nerves of external sensation.

I have lastly to speak of the intellectual act of perception; and with this I shall associate, as our time is limited, something that goes rather higher than perception—what we call "common sense." Our perceptions are the mental judgments which we pass upon the materials furnished by our sensations. These judgments may relate simply to the nature of the external object which calls forth our sensational consciousness. Thus, I have a number of sensations connected with an orange. I recognize its form and color, and the character of its surface, as made known to me by my sight; and then I have other remembered sensations of its aspect when cut open, of its fragrant smell, and its pleasant taste, all of which are embodied in my conception of an orange. And the recognition of the object, as distinct from my own consciousness of the sensorial change excited by its presence, is what we mean by *perception*.

Now, as the first element in all perception is the recognition of the externality of the object, of the presence of something that is outside ourselves, we are brought into contact with a question which (as you must all know) has been debated by philosophers from the beginning of philosophical thought, namely, the reason why we thus project our consciousness, as it were, into the outside world, and the basis of our conviction that there *is* an outside world. All of you who have read Berkeley, and studied him as he ought to be studied, will be aware that Berkeley traced everything back to our own subjectivity—that is, to each individual's recognition of changes in his own states of consciousness. And, in regard to this point, I believe that every scientific psychologist of the present time is a follower of Berkeley. But when we further inquire, as metaphysicians do, *why* we infer the existence of objects external to ourselves from changes within ourselves, we find logical proof altogether wanting, every philosopher being able to pick a hole in every other philosopher's train of reasoning. My own conviction is that we believe in an external world simply because we can not help it, the conviction being forced upon us by the automatic work of the Ego in the combination of a vast number of different experiences, every one of which *suggests* the conclusion, while the concurrence of all forces this conclusion upon the mind as an unmistakable conviction. And this seems to me to be the basis of the distinction between that purely subjective state which we call dreaming and the state of ordinary consciousness

* Having had the opportunity of carefully perusing Dr. Clarke's treatise, subsequently to this mention of it, I have pleasure in recommending it to all who are interested in this inquiry, as, in my judgment, a sound and well-digested exposition of its subject, which must have been well thought out by its able author while his intellect was yet in its full vigor.

in which we recognize the reality of an external world. It is the belief of some psychologists that there is so little fundamental difference between these two states that, in an early stage of intellectual development, man is liable to confuse his dreams with his waking states. I am myself perfectly willing to admit the possibility of this, because I think we have all an occasional tendency to confuse our dreams with our waking states, when our dreams consist of successions of ideas that *might* have had a foundation in reality. Although, as a general fact, our dreams are exceedingly incoherent, and rapidly fade from the memory, yet we are sometimes vividly conscious during sleep of ideas which have an unusual *vraisemblance* and consistency; and when these reproduce themselves in our waking state—a few days afterward, it may be—we say, “Did I hear such and such a thing, or did I dream it?” It is only when our dreams are thus consistent with our every-day experience that we have any difficulty in distinguishing them from our waking consciousness. Their unreality is generally made apparent to us on waking by their marked inconsistency with assured facts; as, for example, when we have been talking (as we thought) with persons whom we know to have been long dead. As Tennyson has said, “Dreams are true while they last;” it is when we awake to the realities of the world that their unreality is made obvious to us—our disposition to believe in our own states of consciousness being here negated by being brought to the test of our surest convictions. Our disposition to believe in the reality of an external world, on the other hand, is receiving constant confirmation from so great a number and variety of experiences that we regard the denial of it as an affront to our “common sense.”

Now, an analysis of this and other deliverances of that “common sense” upon which a great part of our every-day conduct is based, has led me to regard it as the *integration* of a vast number of separate experiences, effected by the automatic action of that elementary intellectual apparatus (if I may so express myself) which is common to every individual. And I shall endeavor to make my meaning clear to you by an illustration derived from a very remarkable machine which my friend Sir William Thomson, of Glasgow, has devised for the calculation of tides. Every one knows that the rise and fall of the tides depends essentially upon the attraction of the sun and the moon; and that these differ, both relatively and absolutely, according to the period of the lunation. Thus, at new and full moon, the two attractions concur, and we have spring tides, while at the quarters they are opposed, and we have neap tides. So, the orbit of the moon being elliptical, when she is nearest the earth (or in perigee) her attraction is stronger than it is when she is at her greatest distance from the earth (or in apogee). Again, as the earth's orbit also is elliptical, the sun's attraction is greater at the earth's least distance from it (perihelion) than it is at her greatest distance (aphelion). There are several other inequalities in solar and lunar attraction and motion, which have a constant regular operation that is capable of being calculated for any particular place. And, besides all these, there are other factors arising out of the local conditions of the place. Altogether, I think

there are as many as eleven different variables, every one of which has to be taken into account, in combination with all the rest, if you would calculate the rise and fall of the tide and the time of high water for any particular place. Now, Sir William Thomson has constructed a most ingenious machine, which works out this resultant automatically, when adjusted in the first instance for the special peculiarities of the locality; so that when these adjustments have been made, and the machine is put in action by turning a handle, the required time-table is evolved by it, as the general resultant of the whole series of independent factors.

Now, this is what I think that the automatic action of our cerebrum is constantly doing for us—integrating, as it were, all our diversified experiences in one resultant, which impresses us with the conviction of its certainty, in virtue of its complete consistency, not only with the whole aggregate of our remembered experiences, but with every new experience as it arises, so as to leave no loop-hole for doubt or hesitation. For example, I might put the question to myself, “How do I know that I am not in a dream at this very moment?” I have often dreamed of lecturing; and if I have been about to begin a new course of lectures, about which I have been a little nervous, I have not unfrequently dreamed that I had overslept myself, and have been too late for my lecture, and that some very unpleasant consequences had followed. But while the objective reality of these conceptions has been disproved by their inconsistency with my waking consciousness, every impression made upon my consciousness in connection with this course of lectures fits into every other impression; there is a perfect congruity and harmony in the whole series of those impressions; and, therefore, I feel perfectly satisfied that I am not under any delusion in the matter.

I have no hesitation, then, in basing my conviction of the reality of an external world upon the general accordance of my sense-experiences, each of these affections of my consciousness suggesting to me an external or objective cause for it, and my visual sense in particular projecting the object into outer space, just as my tactile sense makes me locate an impression received through it in my finger-ends, and attribute it to some object in contact with them. And this conviction is not weakened by the knowledge that any individual experience may be interpreted wrongly, visual images, for instance, occasionally presenting themselves without any object answering to them, and tactile impressions being felt after the loss of the limb to which they are referred. For in each of these cases the objective unreality is at once proved, and the correction supplied, by that very comparison of experiences in whose results, when accordant, we seem fully justified in placing implicit confidence. For, when we try to grasp the spectral figures which our diseased brain has conjured up, we find them to consist of shadow without substance; and, when a man who has suffered amputation looks for the hand whose fingers he seems to himself to be moving, he becomes sadly conscious of his loss.

Every metaphysical system which bases the argument for the reality of an external world upon the necessity of so interpreting any single sense-impression, seems to me open to the very obvious physiological objection that this sense-

impression may be purely subjective. But, on the other hand, I hold that we are under the absolute necessity, in virtue of the original constitution of our minds, of so interpreting that integrated resultant of all our sense-experiences, which is worked out for us automatically by our cerebral, or, as some may prefer to call it, our mental mechanism.

I must postpone until the next lecture the evidence of this integrating action that may be drawn from that co-ordination of our visual and tactile sensations, on which we depend for our recognition of solid form, confining myself, at present, to the remark that here again each sense corrects and checks the other. A well-painted "scene," viewed from a distance, may give an entirely false conception of the relative positions of the objects it represents, while no handling of any object by a person born blind will give him a true conception of the form of that object as *seen* by him when he first acquires visual power. And I shall bring the present lecture to a close by giving you a curious instance in which a perceptive judgment, based on visual experience alone, is proved to be altogether false by bringing it to the test of *comparative* experience.

I place before you these two pieces of card, one above the other; and I think that if I were to ask any one who sees them to say, "off-hand," which of them is the larger, he (or she) would unhesitatingly reply, "The lower one." If you do not take time for consideration, but judge by your first impression, I believe that you would all agree in this verdict. But I now take up the lower card and place it above that which was previously the higher; and you then see that it looks just as much *smaller* than the other as it previously looked *larger*. I now lay the one upon the other, and you see that they are of exactly the same size. The illusion is so complete as almost to suggest jugglery; but you may readily test it for yourself by drawing the figures with a pair of compasses and a ruler, and then cutting it out in duplicate.

It is easy to see, on a little consideration, that our erroneous *prima facie* interpretation has been suggested by the *convergence* of the two lateral borders; so that those of the upper card, when mentally prolonged downward, fall much within those of the lower. If these lateral borders be made *vertical*, the equality of the two cards becomes at once apparent, as it does when you direct your attention to the fact that the higher and lower corners of the upper card, respectively, lie vertically above the higher and lower corners of the under one.

Now, this simple case of perceptive illusion appears to me an extremely valuable one, as showing how easily we may be misled in the *interpretation* of our sensations by suggestive promptings that operate through our automatic mechanism. Such suggestions as I shall show you in the next lecture exercise a very curious disturbing influence on our appreciations of the size and distance of objects not near enough to be apprehended by the touch; and when we pass into that higher region, in which our ideas are associated with states of feeling that give them an emotional character, we shall find that, in order to prevent ourselves from being led astray by them, it is continually necessary to keep our automatism in order by a comparison of experi-

ences, and to direct our course of thought and feeling by that selective attention upon which I have dwelt so much this evening.

Original Communications.

THE PATHOLOGY AND RADICAL CURE OF HAY FEVER, OR HAY ASTHMA.*

By JOHN O. ROE, M. D.,

ROCHESTER, N. Y.

FELLOW OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, MEMBER OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, OF THE AMERICAN MEDICAL ASSOCIATION, ETC., ETC.

ALL writers on hay fever, with a marked unanimity, agree that it is a most singular disease, that its cause is uncertain, that its pathology is unknown, and its treatment most unsatisfactory.

This absence of definite knowledge concerning it has arisen, not from lack of patient, careful, and close observation to determine its causes, but from the fact that these causes have been studied independently, that their relations to the tissue in the nasal passages, which is the part especially affected in this disease, have not been taken into consideration, and that the conditions in this tissue which render it susceptible to these influences have been entirely overlooked.

This fact is especially significant, for, in the examination of the various and more or less elaborate works on hay fever, we find no mention of any examination into the objective condition of the nasal passages, nor of any investigation as to the existence of any localized diseased condition which may predispose to the affection.

This is made more conspicuous when we consider the amount of labor expended during the past few years by the many hard workers, who have been carefully investigating the conditions of the tissue of the nasal cavity to discover the cause and means of cure of chronic nasal catarrh.

These investigations have revealed that the cause of nearly all of the most obstinate forms of nasal diseases, which have been considered incurable, can be removed, and the diseases more or less effectually and permanently cured.

These studies have also shown the nose to be a very important organ for maintaining in a normal condition all the organs with which it communicates, and have revealed relations existing between diseases of the nasal cavities and disorders of other and sometimes distant organs, which were before unsuspected.

As a further result of these investigations, it is clearly demonstrable that the special cause for hay fever does not alone reside in a special peculiarity of a special irritant which affects certain individuals in a peculiar manner, but in a special susceptibility of the tissue of the nasal passages of some individuals to be irritated by these substances when brought in contact with it; that this susceptibility of this tissue is occasioned by disease, either latent or active; that

* Read before the Medical Society of the State of New York, Albany, February 6, 1883.

the removal of this diseased tissue will remove the susceptibility to irritation by these substances; and that the train of symptoms which appear to be more or less of a constitutional nature, producing the asthmatic and nervous symptoms (which have led to the classification of the affection as a neurosis), is but the result of the irritation of the Schneiderian mucous membrane, which is reflected to other parts and organs through the agency of the sympathetic nervous system, causing irritation in these organs, which is augmented by the consequent obstruction to nasal respiration during the attack.

In the attempt to discover the cause and to explain the pathology of this affection, variously called hay fever, hay asthma, grass asthma, rose cold, June cold, peach cold, ragweed fever, pollen fever or pollen catarrh, *catarrhus æstivus* (or summer catarrh), autumnal catarrh, etc., three theories have been brought forward to explain its phenomena:

1st. That it is caused by the pollen of certain plants and grasses floating in the atmosphere, which, being inhaled into the nasal passages, produces in them a special irritation, which excites more or less systemic disturbance in other organs.

2d. That it is caused by the lodgment or development in the nasal passages of vibrios or minute organisms which induce the attendant symptoms.

3d. That it is a functional disease of the nervous system, a neurosis.

Hay fever has also been attributed to the influence of heat and light, and to the odor of certain animals and plants.

The first, or pollen theory, originated with the laity in England in 1819. They observed that their annual attack of this affection was coincident with the ripening of grasses and the mowing of hay, and therefore attributed it to the inhalation of the pollen given off from the ripened grasses. Thus arose the terms hay fever and hay asthma. This theory is the one generally held at the present time, and it is supported by the largest number of experimental observations.

The second theory originated with Helmholtz, in 1868, by his discovering in the secretions from his own nose vibrios or minute organisms, to which he ascribed his hay fever, for the reason that they could not be found in the secretions from his nose when free from the disease. In his letter communicating his discovery to Professor Binz, who first made it public (*Virchow's "Archives,"* vol. xlv., p. 100), Helmholtz himself does not charge them with being the cause, but only with increasing the irritation.

In 1873 Dr. Salisbury ("*Infusorial Catarrh and Asthma*") discovered an animalcular organism which he called the *asthmatus ciliaris*, and to which he attributed the hay fever. This parasite is said to inhabit stagnant and running water, and to be developed in fermenting organic matter.

This animalcular theory has had many advocates, largely owing to the encouragement which it has received from the believers in the germ theory of disease; but as yet it has not been confirmed by other scientific and careful observers.

The third theory, that it is a functional disease of the nervous system, was brought forward mainly by the late

Dr. Beard, of New York, in his work on "Hay Fever." (New York, 1876.)

In ascribing the cause of the disease to the nervous system to explain the nervous phenomena which so frequently accompanied it, Dr. Beard evidently mistook the effect for the cause, since all these symptoms can be much more satisfactorily explained as arising by reflex irritation from the local affection in the manner already referred to.

A constitutional cause seems quite incapable of being the explanation of the annual recurrence of the disease at a definite season, and often at a definite day or hour, in persons in undoubted health and entirely free from all possible trace of nervous disorders during the remainder of the year.

The dependence of this affection upon the presence of pollen and other irritating substances floating in the atmosphere has been, by the most careful researches, conclusively established.

Dr. Blakeley, in his elaborate researches, found that during the summer months the atmosphere of certain localities, often to the height of from 1,000 to 1,500 feet, contains pollen grains in varying quantities, and that a small portion of this substance, even less than $\frac{1}{100}$ of a grain in weight, if directly applied to the mucous membrane of the nose of certain individuals, causes, within five minutes, occlusion of the nasal passages, with sneezing and lachrymation. This irritating effect is possessed by the pollen of all plants, but more especially by that of the Gramineæ. ("*Hay Fever*," Manchester, 1880, second edition.)

The action of pollen upon the mucous membrane is explained by Berkart ("*Asthma: its Pathology and Treatment*," London, 1878, p. 146) in its behavior upon contact with water vapor and also with mucus, according to the observations of Lûhe.

Under the microscope, pollen appears as a simple cell, with granular contents and a cell-wall, consisting of an outer and an inner membrane. The extine is coated with an oleo-resin of a rich amber color, or at times a pale straw color, and contains several slits or pores, across which the intine is stretched so as to impede the escape of the granular matter. It does not appear that the oleo-resin has any specific action beyond enabling the grains to adhere to objects to which they may approach. On the addition of fluid, the cell is distended; the inner membrane projects through the slits of the outer in the shape of small mastoid processes, to which the granules are attached. A further distension causes the membrane to burst, and the granular contents are, with considerable force, ejaculated into the surrounding fluid. These granules irritate the mucous membrane, especially the mucous glands, and reappear finally in the sputa, resembling *zoöglæa* masses.

It has been shown by Dr. Beard that the pollen of plants is by no means the only cause for these symptoms termed hay fever.

The most common cause has been shown by Dr. Beard to be dust in its various forms. In the 200 replies which he received to his letter of inquiry, coming mostly from the laity and which formed the basis for his book on "Hay Fever," dust (indoor and outdoor) is given as a cause 104 times, while hay (dried or fresh) but 38 times, flowers 31,

smoke 27, dampness 29, chills 25, cinders 23, brimstone matches 23, gas 23, fruit 22, cold winds 19, drafts of air 16, perfumes 13, roses 5, etc., enumerating in all 30 different causes.

To account for the preponderance of instances in which the individuals ascribed the cause of their attacks to dust, as stated by Dr. Beard, Dr. Blakeley says it should not be overlooked that nearly all forms of dust, during the hay-fever season, are more or less loaded with various kinds of pollen, as an examination of the dust will readily show.

Thus, we see that with these numerous and widely diversified causes we would be led to look to the parts affected for the explanation of the phenomena to discover why the inhalation of this diversified "invisible nastiness" (as Tyndall very appropriately terms it) should so often produce this common result.

Those who still believe in the nervous origin of the disease will ask: If the affection be due to a local cause, how is it that it will appear in persons each year on exactly the same day, and even at the same hour? These individuals are undoubtedly affected by the pollen of certain plants, and the precision with which some plants ripen annually all botanists know. This is also shown by the fact that on removal of the individual to a seaport or to a mountainous region, or to any other locality where the pollen of these plants is not found, he remains entirely exempt.

Accepting the local irritant theory as the true or only satisfactory one, we will briefly endeavor to show, anatomically and pathologically, how the train of symptoms—as, turgescence of the nasal mucous membrane, lachrymation, sneezing, asthma, etc.—follows as a result of these irritating substances lodging in the nasal passages.

Covering the inferior turbinated bones and the lower part of the septum there is a highly vascular erectile tissue analogous to the cavernous tissue of the genital organs, to which Professor Bigelow, of Boston, has given the name of turbinated corpora cavernosa. ("Boston Medical and Surgical Journal," April 29, 1875, vol. xcii, p. 489.)

This vascular erectile tissue is directly under the control of the vaso-motor nerves, and is exceedingly sensitive to impressions applied not only locally to the part, but to other portions of the body. Often it may be noticed that a draft of cold air striking another portion of the body will cause this tissue to become engorged sufficiently to occlude one or sometimes both nostrils, and it is the involvement of this tissue which causes the distressing sensations arising from a cold in the head.

Sometimes slight disease or hypertrophy of this tissue, and not sufficient to give the patient any special annoyance, will increase its susceptibility to irritation to a marked degree, and it is the irritation reflected from this tissue, through the sympathetic nerves to other parts and organs, which, as I shall endeavor to show, is the excitator of the varied and distressing symptoms complained of by hay-fever sufferers.

It is proved by experiments on animals that violent irritation of the Schneiderian mucous membrane will induce, through the sympathetic nerves, congestion and irritation in the larynx and lungs similar, though in a less degree, to

the derangements induced in the lungs by irritation of the larynx.

The most recent investigations of the sympathetic nerve-centers show that they possess in a marked degree a correlating function between near and distant organs.

This fact is clearly pointed out by Dr. Edmond Woakes in a very able article on the "Correlating Function of the Sympathetic Ganglia," read before the International Medical Congress held at London, August, 1881. ("Transactions," vol. ii, p. 75.)

He showed that the "afferent fibrillæ of a sympathetic ganglion, which are for the most part associated with sensori-motor nerves, are in reflex relationship with the efferent vaso-motor nerve furnished to the arteries from the same ganglion which receives the afferent fasciculi. In other words, an excitato-vaso-motor function is established between the afferent and efferent elements of a given sympathetic ganglion. It is in this sense that these organs are said to exercise a correlating function in regard to such operations as belong to them, between tissue areas often widely separated."

It was first observed by Drs. S. Weir Mitchell, Morehouse, and Keen (in their work on "Gunshot Wounds and other Injuries of the Nerves," Philadelphia, 1864), that falling down, and sometimes momentary loss of consciousness, resulted from gunshot wounds of the brachial plexus, whether inflicted in the upper arm or neck, and was produced by the vessel dilatation in the brain caused by the reflex irritation through the inferior cervical ganglion. It is also well known by physiologists, as was first shown by Claude Bernard, that irritation of the fifth pair of nerves causes the side of the face to become red, the conjunctiva red, and its vessels congested.

Taking, for example, the frequent occurrence of giddiness or vertigo and noises in the head from deranged digestion, which has been so unaccountable, Dr. Woakes shows that it is due to congestion of the labyrinth from the vessel dilatation caused by the reflected sympathetic irritation from the stomach.

We have many other practical illustrations of this correlating function through the sympathetic nerve between near and distant organs.

Irritation of the larynx attended with cough is not infrequently induced by disease or by foreign bodies in the external ear. It is to be observed frequently that, in persons with apparently sound ears, even the placing of the end of the finger in the external auditory canal will provoke a violent paroxysm of coughing and engorgement of the vessels of the larynx.

This sympathetic irritation also exists between the larynx and ear in an inverse order, as shown by the severe earache so often produced by ulceration of the larynx. Otalgia, congestion, and inflammation leading to suppuration of the middle ear are not infrequently produced by diseased teeth, and also by disease in the nasal cavity unaccompanied by occlusion of the Eustachian tube.

A close sympathy also exists between the lachrymal apparatus and the nose, as seen by the marked and almost instant congestion of the conjunctiva and suffusion of the

eyes which follow the application of an irritant to the Schneiderian membrane.

This sympathetic connection between the different organs explains the frequent derangement of one organ caused by disease in another and sometimes distant organ, and is shown by the instances of laryngeal congestion and violent cough produced by irritation and disease of the uterus and its appendages.

Between the nose and the larynx a close and intimate relation exists. It is now a well-established fact with laryngologists that many cases of laryngeal hyperæmia and laryngeal irritation are induced entirely by disease in the nasal cavity through the sympathetic nervous communication between the two regions.

Voltoini first pointed out that many cases of asthma are provoked by the irritation from nasal polypi. ("Galvano-Kaustic," S. 246, u. 312, 1871.) Traube was the first to believe that a fluctuatory hyperæmia of the bronchial mucous membrane was the sole cause of dyspneal attacks ("Bemerkungen über cardiales Asthma," "Ges. Beitr. zur Path. und Physiol.," Berlin, 1878, Bd. iii, p. 209), and later investigations prove conclusively that engorgement of the pulmonary vessels does take place through vaso-motor nervous influence in the manner already described. Several careful observers, as Fränkel, Weber, Schaeffer, Bresgen, Biermer, Mulhall, and some others, believe that in many instances asthma, produced by this fluctuatory hyperæmia of the bronchial mucous membrane, is caused by irritation or disease of the terminal fibers of the nerves supplying the nasal cavity. This is observed more often in cases of chronic hypertrophic nasal catarrh, and is verified by the disappearance of the asthmatic symptoms on the removal of the cause in the nose.

In this manner is explained the intimate connection which so often is seen between these different regions. Thus, irritation of the terminal fibers of the sphenopalatine ganglion is communicated to the Gasserian ganglion which is located in the sensory root of the fifth; this communicates with the carotid plexus of the superior cervical ganglion of the sympathetic; this in turn communicates with the pneumogastric, which distributes its fibers to the larynx, lungs, heart, œsophagus, stomach, intestines, etc. We also have the otic ganglion, the ophthalmic ganglion, the maxillary ganglion, and the superior and inferior dental nerves all united in common through the sympathetic, in this beautiful system of nervous communication, and any or all of the parts may suffer from irritation set up in any one part, however remote it may be.

(To be concluded.)

THE NEW YORK CODE OF ETHICS.*

By C. B. HIGGINS, M. D.,

PERU, INDIANA.

THE adoption by the State Medical Society of New York of a code of ethics in conflict with that of the American Medical Association has been productive of much discussion, both for and against the innovation. At the last

* Read before the Eleventh District Medical Society of Indiana, at Marion, April 17, 1883. The society passed a resolution requesting the author to publish the paper in a journal of his own selecting.

meeting of the American Association, the action of the New York society was almost unanimously condemned, and, so far as I know, the position taken at St. Paul has been indorsed by a majority of the regular profession in this country.

I propose to-day to offer a few reasons why the course of the New York society should be sustained. In presenting my views on this subject, I shall notice but one of the objections advanced by the opponents of the change, and will lay no claim to originality, for the question has been so thoroughly discussed that it would be difficult to offer anything new. The principal objection urged against the new code is that it "obliterates the broad distinction which was previously easily recognized between scientific medicine and medical charlatanism." Were the ignorant and uncultivated alone imposed upon by charlatans, this objection would be insurmountable; but that such is not the case may be easily shown. From the time of the Æsculapian priests to the present there has never been originated a system of medicine, no matter how absurd, but that it has succeeded in securing the confidence and support of intelligent and thinking men. There is a trace of superstition in all of us which, fight it as we may, will influence, to a greater or less extent, our thoughts and actions. The recent weather predictions of the Canadian, Wiggins, illustrate in a striking manner the influence a positive and enthusiastic mountebank may have on the public mind. Thousands of well-informed people confidently expected the fulfillment of the weather quack's prognostications, and a number of newspapers (molders of public opinion) went so far as to publish maps describing the course of the expected storm. An ex-United States senator and cabinet minister recently horrified the religious world by giving a fashionable reception at his new home in Washington city on the Sunday evening preceding his daughter's marriage; the cause of this strange breach of social custom was the senator's fear that ill-luck would attend the house whose first hospitality was dispensed at a wedding.

Macaulay, in speaking of the liability of persons of learning and probity to become enlisted in the cause of new and fanciful forms of religion, says: "The truth is that no powers of mind constitute a security against errors of this description." The same may with propriety be said of those vigorous intellects which have been led astray by medical delusions.

With merely an allusion to the absurd practices which characterized the treatment of disease by the Æsculapian priests and the followers of Pythagoras, to whom scientific medicine owes its origin, I will pass to a more recent period for examples to illustrate this point. Paracelsus, the notorious quack who flourished in the sixteenth century, succeeded so well in imposing upon educated people as to secure the appointment of professor of physic and surgery in the university of Basel, and was for a time the leading medical man of continental Europe; the philosopher Erasmus, the most learned man of his day, was his friend and patron; to this "ignorant boaster" we are indebted for the introduction into the materia medica of one of our most valuable remedies. Cagliostro, "the quack of quacks," as Carlyle

styles him, in the latter half of the eighteenth century, was successful in duping the highest dignitaries of the countries which he visited; among the most ardent of this charlatan's supporters was a cardinal of the Roman Church. In our own time numerous distinguished examples can be found to sustain this position. The late President Garfield was a believer in the power of homœopathic pellets to combat disease. The distinguished senator before alluded to as having given the Sunday reception is an ostentatious advocate of the saving power of infinitesimal dilutions. The late Lord Beaconsfield, by reason of having employed a disciple of Hahnemann during his last illness, was the cause of a good deal of discussion on the subject of medical ethics.

In our own State a notorious specialist, who travels from town to town professing to cure consumption, issues handbills in which are printed certificates signed by an ex-governor of the State and by a bishop of a prominent religious body indorsing him as a skillful physician. A Cincinnati medical journal, a few months ago, in an editorial notice of the distinguished English physiologist, Professor W. B. Carpenter, expressed surprise that he should be a member of the Unitarian Church, as among his (the editor's) acquaintances of professors of that faith he knew no one who was not a homœopathist. I think these illustrations will serve to show that the patrons of charlatans are not found exclusively among the ignorant.

However much we may boast of modern progress and the superlative intelligence of this generation, there is no denying the fact that in the minds of a great many long-headed people the art of medicine is still associated with the supernatural; and, while humanity is obnoxious to incurable and fatal maladies, charlatany will thrive, and the question for friends of scientific medicine to determine is, how best to restrain its advance and render it least harmful.

In continental Europe the members of the regular profession have never found it necessary to publish to the world a code of ethics declaring with whom they would or would not consult; they do not consider such action necessary in order to preserve the broad distinction which exists between scientific medicine and medical charlatany; "there irregular physicians are not ostracized, but simply regarded as persons holding rather remarkable views concerning the action of medicines." In no countries is the regular school of medicine in higher standing, nor are irregulars less regarded, than in Germany, Austria, and France. In the United States and England, where it has been deemed essential, in order to protect the public, to publish a code of ethics declaring that irregulars were unworthy of confidence and unfit persons to meet in consultation, the effect has been to create a popular prejudice in favor of any school that may spring up in opposition to the old one. In this connection I will read an extract from a letter written to a Western medical journal by a physician in Philadelphia, explaining why it is that the profession there is annoyed to a less degree by irregulars and charlatans than in any large city in the country.

"Quacks are systematically ignored. They are treated

with uniform politeness, but kept at a distance, so that no discussion or dispute may give them the opportunity of claiming sympathy by raising the cry of persecution. No member has yet been excluded from the county society simply because he has adopted some exclusive practice; in other words, he is not hustled out simply because he is a homœopath, but he generally finds that the atmosphere is not congenial, and either sends in his resignation, or is dropped for non-payment of dues. In this way he is deprived of a gratuitous advertisement in the daily papers as a first-water martyr, and, instead of winning popular sympathy, he has no notice taken of him whatever, and he returns to obscurity."

This is a remarkable statement coming from Philadelphia, where the profession is almost a unit in opposition to the revised code. If this is not ignoring the old code in so far as it pertains to association with irregulars, I am unable to interpret its meaning.

That Drs. Agnew and Hamilton, whom we all honor for their eminent attainments, have not been disciplined by their respective county societies for consulting with the motley crowd that surrounded and ministered to the lamented Garfield on his death-bed, has not excited any special wonder. Owing to the prominence of the patient, to have refused attendance upon the case would have been professional suicide. If men in the higher walks of the profession may ignore the code in the case of a president, why may not the cross-roads physician, without fear of professional disgrace, offer suggestions to the "cow doctor" who is perchance in attendance upon the village shoemaker?

There is an inherent tendency in almost every man to champion the cause of the weaker party in any contest the origin of which is unknown to him, and the originators of new systems of medicine, the publishers of patent medicine almanacs, and others who are seeking recognition without reference to the merit of their claims, take advantage of this well-known phase of human weakness, and, when their pet schemes are attacked, raise the cry of persecution, generally to the discomfiture of the attacking party.

When the New York society made their now celebrated move in revising their code of ethics, the representative journals of irregular medicine, the country over, were loud and elaborate in derision of the action, realizing as they did that this step forward on the part of a few of the most prominent and intelligent physicians in the country would eventually result in depriving them of one of the main agencies which had been contributing to their advancement.

I would not advise any member of the regular profession to affiliate with irregulars, but I think it is a duty we owe to the cause of scientific medicine, and to the public, to remove from our code of ethics everything that can in any way promote the interests of charlatany, and in our published proceedings to let nothing appear which will create sympathy for quackery.

As some one said when asked to prepare an article in refutation of some theory of the alchemists, "Let them decay in their own absurdity."

NOTES UPON CRYSTALLINE ELATERIN.*

By GASPAR GRISWOLD, M. D.

ELATERIUM is certainly the best of the hydragogue cathartics, but it has of late fallen into great disfavor because different specimens of it vary so widely in strength. The market contains many preparations labeled "Dose, $\frac{1}{30}$ grain," of which, notwithstanding, as much as a grain may be given without producing any more effect than the same quantity of aloes. From this has arisen a lack of confidence in elaterium which deters many from prescribing it, especially in those critical cases in which it should find its best application.

The variations in the strength of elaterium are at once explained when we look at the manner in which it is prepared. The fruit, or cucumber, contains a central cavity filled with seeds floating in a fluid. If this fluid be poured into a flat dish and allowed to stand for an hour or two, a thin layer of sediment is deposited which is largely made up of crystals, the remainder consisting of resins and extractive substances. This sediment contains the purgative properties of the plant in great concentration; it is not deposited as a result of evaporation, but resembles rather a precipitate caused by some chemical action of the atmosphere upon the fluid. This sediment is so scanty that Clutterbuck obtained only six grains of it from forty cucumbers. If attempts be made to increase the sediment, either by evaporating the fluid or by adding to it the juice squeezed from the fruit, the substance so obtained is much less powerful than the original scanty sediment, and is observed to contain a larger proportion of resins and extractives, with very few crystals. The crystals were first isolated by Morries in 1831; he found that they possessed the characteristic purgative properties of elaterium, and that elaterium from which the crystals had been extracted was inert. He, therefore, concluded that the crystals constituted the active principle, and called them *elaterin*. Unfortunately, the name *elaterin* has since been loosely applied to various extracts of *elaterium*; only the true active principle is *crystalline*, however, and it is in that way easy to distinguish it.

From this short account it will be clear that good elaterium should consist exclusively of the first scanty sediment from the juice found free in the cavity of the cucumber; and that any attempt to obtain more of the drug by squeezing the fruit or evaporating the juice is attended with a deterioration in the quality of the article produced. In this way we have *elaterium fuscum*, *elaterium viride*, and *elaterium album*, all varying in strength, but differing from each other merely in the amount of inert extractive substances which they contain. No elaterium is at present manufactured which bears the name of Clutterbuck on the label, but George Allen & Co., of London, put up the first scanty sediment after Clutterbuck's method, and this is sold by McKesson & Robbins as Clutterbuck's elaterium.

Where the crude drug is subject to so much variation it is especially desirable to find an active principle which may

be relied upon, and, above all, one whose occurrence in definite crystalline form enables us to determine that it is free from adulterations or impurities. It is only necessary to call attention to the superiority of crystalline *aconitine* and *hyoscyamine* over the amorphous forms of the same, to show what an advantage crystalline *elaterin* possesses over the various amorphous extracts which bear the name. This advantage seems so obvious that it is hard to understand why crystalline *elaterin* did not at once take the place of all the unreliable preparations of elaterium; and yet two months ago not one dispensing druggist in the city had ever had a grain of crystalline *elaterin* in the shop! McKesson & Robbins and Eimer and Amend have had on hand for some years Merck's *crystalline elaterin*, but have never sold any. Many druggists answered in the affirmative when asked by the author if they had *elaterin*, but the article, when produced, always proved to be some amorphous extract.

The author obtained some of Merck's preparation from McKesson & Robbins, and found it to consist of white hexagonal crystals, as described by Morries in 1831, soluble in chloroform and in alcohol, but insoluble in water and ether. To test it clinically, the author has, during the last six months, given it to thirty-two patients in private practice, in the dose of one tenth of a grain, repeated in four hours if necessary. In nineteen of the cases one dose was sufficient; in nine cases the second dose was also taken; and in five cases the third dose was administered. In every instance the watery evacuations followed which characterized the action of elaterium. One patient, who was suffering from dropsy and chronic uræmia, took the remedy on four occasions in the course of three months, each time with great temporary relief. The drug was also given for me in twenty-eight cases in the Brooklyn City Hospital by Dr. William A. Pierrepont, the resident physician. I have received quite a full report of these cases, from which it appears that the crystalline *elaterin* acted as an efficient hydragogue cathartic throughout. It produced a remarkable result in one case of excessive dropsy from acute Bright's disease; the patient was a very large man, weighing 390 pounds on admission, and measuring 63 inches around the waist. After a week's treatment with *elaterin*, his weight had fallen to 316 pounds, his waist only measured 50 inches (only two inches more than his girth in health), and albumin had disappeared from the urine. In ten days he was far advanced in convalescence, and able to walk about.

The facts detailed in this paper seem to warrant the following conclusions:

"1. That the crystalline *elaterin* of Merck, now for sale in this city, is identical with that discovered by Morries in 1831, and is the active principle of elaterium.

2. That its definite crystalline form and freedom from impurity render it more reliable than any preparation of elaterium.

3. That the proper dose to commence with is one tenth of a grain; and that this may be prescribed in a solution of one grain of *elaterin* to half an ounce of alcohol, or in the form of tablet triturates, containing each one tenth of a grain. The last can be had at Fraser & Co.'s pharmacy.

Clinical Reports.

NEW YORK HOSPITAL.

INTERNAL URETHROTOMY. HYDRARTHROSIS OF THE KNEE—SCHEDE'S TREATMENT. NECROSIS OF THE TIBIA, INVOLVING THE JOINT—AMPUTATION OF THE THIGH.

Clinical Remarks

By ROBERT F. WEIR, M.D.

II.

(Reported by R. C. SHULTZ, M.D.)

GENTLEMEN: The first operation which it is proposed to perform to-day is that of internal urethrotomy for the relief of a urethral stricture. Those of you who were present at the last clinic may be interested to know the result of the same operation performed upon another patient on that day. I am sorry to have to say that the result was not a good one; the patient died. You will remember I stated that the percentage of mortality, both from internal urethrotomy and from dilatation, was very small, and that there was very little difference indeed in favor of the latter mode of treatment. That internal urethrotomy had a death-rate, in 800 cases collected by Gregory, of 5.66 per cent.; that of dilatation, in Bryant's 565 cases, there was a mortality of 6 per cent. The past history and the present condition of the patient upon whom I operated on that day were so good as to give reason to believe that the case promised very favorable results; no contra-indication was found in the condition of the kidneys, which, so far as chemical and microscopical examination of the urine went to show, were perfectly healthy. It was believed and remarked upon, when discussing the risks of any urethral treatment, that if the patient should have urethral fever after an operation, he would be able to encounter it without special danger. But these hopes were not fulfilled. The patient passed through the first twenty-four hours after the operation comparatively well. Seventeen ounces of urine were secreted. After that, however, no more urine was passed until the third day, and then only about three ounces, which was withdrawn with the catheter. On the day following the operation the temperature fell to 97.4° F.; on the third day it rose to 105°, being the first evidence of what might be considered inflammatory action. The highest temperature attained was 106° F. The pulse early became very feeble, being inappreciable most of the time at the wrist, and very rapid. There was no hemorrhage from the urethra. An examination of the urine obtained on the third day revealed some blood, pus, albumin, and epithelial and hyaline casts. The treatment consisted in the administration of the infusion of digitalis, of the fluid extract of the lily of the valley, of remedies for the relief of vomiting which occurred on the first day, of counter-irritants over the kidneys in the form of poultices and cups, and of the hot bath. The patient had no convulsion, but became unconscious toward noon of the third day, and died.

The post-mortem examination showed two clean-cut incisions in the urethral canal along its upper surface, one having been made by the urethrotome as it entered, and the other as it was withdrawn; slightly increased redness of the urethral and vesical mucous membrane was also found. The only condition present to account for the fatal result was intense congestion of the kidneys. The microscope revealed no antecedent pathological condition; the trouble was purely acute. I will not stop to theorize upon the probable cause of the nephritis, but will simply say that it may have been of reflex origin—that is to say, due to the irritation of the urethra or bladder, transmitted

to the kidneys by means of the nervous connection between these organs, an explanation we are compelled to accept in such cases as this; or, what is more common, a wave of inflammatory action may start from the urethra, sweep over the bladder and urethra, and in this way invade the kidneys.

Notwithstanding the unfortunate termination of the former case, I shall not hesitate to continue to do the operation in cases in which it seems to hold forth the best prospects of success, as I believe it will do in the case of the patient now before you. This man is thirty-two years of age, and has an antecedent history much more unsatisfactory than that of the former patient. His habits have been irregular; he had gonorrhœa for the first time eight years ago, and has had it a number of times since. Two years ago he noticed that the stream of urine was becoming small and twisted, and he was compelled to empty the bladder more frequently than before. Seven weeks ago he presented himself at the out-patient department of this hospital, and was treated by dilatation. It was observed that when the patient remained away for several days recontraction rapidly took place, and it has been thought best, principally from this fact, to perform internal urethrotomy, which we will now proceed to do. I succeeded yesterday in passing a filiform bougie into the bladder, fitting the stricture snugly, and gave instructions to allow it to remain in until to-day, so that the somewhat large and flexible conducting bougie could be more easily passed; but the house surgeon found that it was necessary to remove it in the course of the night, on account of the irritation that it produced; this is not an infrequent interruption. The situation of the stricture is found to be just anterior to the triangular ligament. In performing the operation after the patient is etherized and the conducting bougie introduced and screwed on, you will observe that I divide the stricture in the same manner as in the former case, passing the cutting edge of the knife of Maisonneuve's instrument along the upper wall of the urethra, by which procedure hemorrhage is avoided, and, after it has cut its way through the stricture, turning it slightly to one side on withdrawing it, thus making two lines of incision through the strictured portion. This plan accomplishes an enlargement sufficient to pass a sound of the caliber No. 32 French, with a blade of 11 mm. in width, which with one cut would only divide to about 26 French.

HYDRARTHROSIS OF THE KNEE—PUNCTURE OF THE JOINT—INJECTION OF CARBOLIC ACID.

CASE II.—Our next patient is a negress, thirty-nine years of age, a laundress by occupation, and in good general health, who is suffering from hydrarthrosis of the knee joint. She fell, and struck the anterior surface of the right knee against a chair a little over a year ago. No marked pain or symptoms of acute inflammation followed, but the joint gradually swelled, and finally reached considerable size. The patient, however, was still able to be about, until six months ago the knee became so weak that it yielded under her weight. There was no special pain. When she entered the hospital, less than a month ago, the knee was enormously swollen, measuring sixteen inches and a half over the patella. An elastic bandage, and subsequently counter-irritants, were applied, but without marked result. The ligaments of the joint are considerably elongated, allowing of pretty free lateral motion and of separating the joint surfaces to some distance, so that they can be knocked together with an appreciable noise. There is at times an outward and backward dislocation of the tibia, to the degree that the external condyle rests on the internal tuberosity of the tibia. The amount of synovial exudation within the joint appears to be very considerable, and it doubtless contains more or less flocculent material. It is very seldom that we meet with a case in which there is so

great relaxation of the ligaments of the joint as exists in this patient. As you see, the leg can be flexed laterally on each side nearly to an angle of 45° . Having failed to produce any marked benefit by counter-irritation and pressure, resort will be made to a method which has lately been considerably practiced by the German surgeons Volkmann and Schede, but originated many years ago, I believe, by Bonnet, of Lyons. It consists in introducing a full-sized trocar into the joint at its outer and upper aspect, and withdrawing the accumulated fluid, and then in washing out the cavity, under considerable pressure, by elevating the reservoir containing the solution some eight or ten feet, with a solution of carbolic acid (1-20) until the injection returns perfectly clear. The operation is done under the spray, and without an anæsthetic. It may be necessary afterward, in case this fails, to follow the plan, largely practiced by Bonnet, of injecting tincture of iodine into the joint cavity, for the purpose of exciting an acute inflammation that shall supersede the old chronic process and lead to a permanent cure; or, as the relaxation of the ligaments is so great, even the more severe operation of excision of the joint may become necessary.

You will observe, after the eight ounces of reddish-colored fluid has been withdrawn, that, after repeated injections, the carbolic solution continues to return slightly tinged red, which doubtless is due to a small amount of oozing of blood within the joint cavity. A Lister dressing is now applied with firm pressure, and the joint immobilized with a plaster bandage.

Schede divides his many cases treated by puncture and washing out of joints into three groups: 1. Those where there is no reaction, or a very moderate one, and no further effusion. In these the joint functions are often fully restored at the end of two or three weeks. 2. Where the reaction shows itself as a mild synovitis which disappears rapidly, either spontaneously or under pressure. 3. Those where there is no reaction, but a recurrence of the effusion, which may disappear quickly or may remain.

To the first and second classes belong the cases of serous effusion without secondary changes, light catarrhal suppurations, and blood extravasations.

To the third class belong the older cases with thickening of the capsule and the perisynovial tissues, and relaxation of the ligaments. These demand energetic irritation and repetition of the injection once or several times, with either stronger solutions of carbolic acid or with tincture of iodine—diluted or of full strength.

His directions concerning the after-treatment of chronic joint effusions managed in this way are to remove the bandage at the end of six days, when the wound will be found closed. The joint may then present itself, either without any effusion or inflammation, in which case the patient is kept in bed two days longer with an elastic flannel bandage and posterior splint, and three days later moderate movements are permitted. In most instances, in two weeks the joint functions are found to be normal. Should, however, an effusion be recognized when the first dressing is applied with a tolerable amount of pain, a longer rest, with some after-compression, may be needed; an acute synovitis is in some cases necessary to a cure.

NECROSIS OF THE HEAD OF THE TIBIA, INVOLVING THE KNEE JOINT —AMPUTATION OF THE THIGH.

CASE III.—This patient has also an affection of the knee joint, which resulted from a blow received upon the anterior surface of the left knee three years ago. Acute synovitis resulted, with slight tenderness and swelling. The joint then became stiff. The patient was soon able to go about on the limb, although he was unable to bend the joint. His knee troubled him in a slight degree from time to time subsequently, but it was

not until three months ago that, after severe exposure, acute inflammation again set in and resulted in an abscess, which opened, and, from the resulting sinus, some small pieces of bone were discharged. On his admission to the hospital, six weeks since, there was only a little elevation of the temperature, but there were present slight night-sweats, and the man's condition in general was rather low. An abscess existed external to the knee joint, which was opened, and it was believed that there was pus in the joint cavity itself, but the point whether the distension was due to serum or other fluid could not be absolutely demonstrated until later, when a spontaneous opening developed. During the improvement of the patient's general condition it was noticed that the interarticular cartilage had disappeared, and that the exposed joint ends of the bone could be made to grate upon each other. Through two of the openings, bone could be detected, and by that over the tibia the probe could be carried into the joint cavity. The man's kidneys seem to be sound, and it is thought best, considering his age (fifty-three years), and the great liability to septic poisoning in such an extensive suppurating surface as this is, to amputate the leg above the knee joint rather than to wait longer with the hope of saving the limb. However, to follow the rule of Mr. Swain, we will first cut down upon the joint, and be guided in our further steps by the condition which it may be found to present.

You will observe, after I have done this, that both the articular cartilage and the bony structure of the joint have been involved in the necrotic process, and that the limb has, therefore, been amputated at the junction of the lower and middle thirds of the thigh above the seat of the abscesses, by a long anterior and a short posterior skin-flap. This method, known as Carden's, though not strictly so in this locality, carries the cicatrix behind the bone out of the line of pressure. It is open to the objection, however, that some risk is met with in the tendency of a long skin-flap to slough.

The wound has been closed, after being washed out with a carbolic solution, by a continuous catgut suture, soaked in sulphurous acid; over this is placed a pad of iodoformed peat, two and a half per cent., and then one of peat that has been immersed in a solution of carbolic acid (1-20), the whole secured by a compressing bandage.

Book Notices.

Spirillum Fever; Synonyms: Famine or Relapsing Fever; as seen in Western India. By H. VANDYKE CARTER, M. D. Lond., Surgeon-Major I. M. D., etc. London: J. & A. Churchill, 1882. Pp. viii+446.

We scarcely know whether to regard it as an unfortunate or a fortunate circumstance that few, if any, such thorough and elaborate monographs as the one before us have been, or are likely to be, issued from the medical press. Certes, if we had a commensurate octavo volume on each of the many hundred ills that flesh is heir to, no one man's lifetime would suffice to master their collective contents. But, judging Dr. Carter's work on its own concrete merits, the most cautious critic could have no hesitation in ranking it as a model of accurate and exhaustive observation, conducted in a truly scientific spirit. Although "relapsing fever" is happily of rare occurrence in the experience of American physicians, it possesses much interest from the fact that it is one of the very few human maladies accompanied by the presence and multiplication of a micro-organism of unmistakable character, and hence affords peculiar advantages for study bearing on the much vexed "germ theory." In

other diseases skilled observers may differ in their descriptions of the alleged specific microphytes. Klebs and Pasteur do not agree as to the appearance of the bacillus of porcine pneumo-enteritis; several different forms of bacteria have been assigned to enteric fever; three or four widely diverse organisms have been credited with the causation of paludal miasm: even the bacillus anthracis is morphologically indistinguishable (except by Koch) from its hay-infusion congener when at rest; and the list of doubts or discrepancies in observation might be tediously extended. But Obermeier's spirochete is recognizable and recognized everywhere, distinctly differentiated from its only competitor, the *S. plicatilis* of water, and figured alike by pathologists in all latitudes where relapsing fever has been studied. It is, therefore, with less uncertain steps than in most other fields of similar inquiry that the relation of the schizophyte to the pathological phenomena can be considered; and to such consideration the author has addressed himself with rare patience and impartiality.

Prior to 1877 relapsing fever had not been recognized in Western India; but, following upon the drought and dearth which then occurred, the disease assumed epidemic proportions, and during the ensuing two years caused an enormous increase of mortality in the infected districts. The actual statistics of its fatality seem uncertain, since the generic term "fever" in India, as elsewhere, serves in mortuary returns to cover a multitude of dubious diagnoses, and many cases of spirillar infection were probably reported under the convenient title of "remittent." The author's own observations in the two hospitals under his supervision cover over six hundred carefully verified instances. From these data is given a minutely detailed clinical history of the disease in all its phases, with its modifications, complications, and sequelæ. Aside from the typically marked cases, we learn of obscurer variations, ranging from a form resembling exanthematic typhus to one mistakable for "febricula"; all, however, having the common diagnostic bond of the presence of spirilla in the blood immediately before and during the febrile stage. Dr. Carter's investigations warrant the assertion that the ætiology of the malady is independent of telluric and climatic influences; that "its essential relations are with poverty as much as famine," over-crowding appearing to be the principal predisposing factor; and that the transference of a specific contagion is demonstrable in most instances and probable in all. The curious phenomena of the rapid disappearance of the spirilla at the close of the pyrexial period, and their almost equally rapid reappearance in the "relapse," naturally point to some hitherto unnoticed stage of their life-history, and the author has observed "minute free particles of rounded form, others elongated, tailed, clubbed or knobbed in the middle; often distinct filaments, short, bent, or even spiral, and in fresh blood not devoid of movement." These, he suggests, may represent the spore development of the spirillum; but, in view of the inherent difficulties of determining the respective rôles of different elements in morbid blood, he does not regard the proposition as proved; it is, however, "noteworthy that these aspects were commonest near the end of specific fever, when the spirillum is about to disappear, and when increased germ-production might be anticipated." Moreover, granular cells and protoplasmic masses, swarming with granules resembling micrococci, were observed during the latter part of the incubation stage, before the appearance of the fully developed spirillum. "Some granule cells were quite peculiar: in them the granules were bright, uniform, and active, and clearly were not fat; they either radiated round a central nucleus, or were disposed in wavy, spiral, or reticulated lines, as if prefiguring some filament within. Sometimes the whole cell was occupied with granules in active swarming movement, which probably escaped by rupture." In

artificial culture experiments, the author's results in the main agree with those of Koch; but, in addition to the aggregation of long interlacing filaments, Dr. Carter has noticed that "often the filaments soon become dotted with bright or opalescent spots, and clusters of bright granules may form at their free ends. Multiplication by segmentation and by growth from bright granules, either attached or free, may be indicated." None save those who have undertaken the study of the life-history of bacterial organisms can appreciate the many sources of fallacy attending such examinations, or sufficiently admire the modest candor of the author as regards observations which the average French or German microscopist would deem an ample basis for any amount of dogmatism. Of the general results we have given but a cursory sketch; for the many minutiae of methods and descriptions we must refer the reader to the book itself, which will fully repay perusal.

BOOKS AND PAMPHLETS RECEIVED.

Medical Essays. 1842-1882. By Oliver Wendell Holmes. Boston: Houghton, Mifflin & Co., 1883. Pp. x-445. [Price, \$2.]

Hand-book of the Diagnosis and Treatment of Diseases of the Throat, Nose, and Naso-Pharynx. By Carl Seiler, M.D., Lecturer on Laryngoscopy at the University of Pennsylvania, etc. Second edition, thoroughly revised and greatly enlarged. With seventy-seven illustrations. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. 295.

Transactions of the Obstetrical Society of London. Vol. XXIV, for the year 1882. London: Longmans, Green & Co., 1883. Pp. lviii-339.

A Reply to "The Academy's" Review of "The Wine Question in the Light of the New Dispensation." By John Ellis, M.D. New York: Published by the author, 1883. Pp. 270.

Woman's Place To-day: Four Lectures in Reply to the Lenten Lectures on "Woman" by the Rev. Morgan Dix, D.D., Rector of Trinity Church, New York. By Lillie Devereux Blake. New York: John W. Lovell Company. Pp. 173. [Price, 20c.]

Twenty-third Annual Report of the Superintendent of the State Asylum for Insane Criminals, Auburn, N. Y., for the year ending September 30, 1882.

Sixty-ninth Annual Report of the Trustees of the Massachusetts General Hospital and McLean Asylum, 1882.

The Pathology and Morbid Anatomy of Tubercle. By N. Senn, M.D., Milwaukee. [Reprint from the "Transactions of the State Medical Society of Wisconsin."]

Case of Radical Cure of Inguinal Hernia: Approximation of the Pillars of the Ring by means of Chronicized Catgut—Recovery. By James Whitsoo, M.D., etc., Glasgow. [Reprint from the "Medical Times and Gazette."]

PERMANGANATE OF POTASSIUM IN DIABETES.—As long ago as 1868, says the "Lancet," permanganate of potash was recommended in diabetes by Sampson, and it has been again tried during the last six years by Masson, who, in a communication to the Académie de Médecine of Brussels, states that he has met with instances in which the treatment was most successful, and others in which it has failed completely. In order to ascertain the reasons for this difference, he excludes the base as probably without any influence; he further expresses his belief that the oxygen is not the active agent, and hence he concludes that its effect must be due to the manganese. He conjectures that its influence is probably exerted on the liver. Manganese is eliminated by this organ, and even small doses injected under the skin cause fatty degeneration of this organ. Masson has further observed that manganese is especially useful in those cases in which there is hepatic engorgement.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 12, 1883.

THE ETHICAL STATUS OF FELLOWS OF THE ACADEMY
OF MEDICINE.

It is acknowledged by many who are opposed to the old code of ethics that all Fellows of the New York Academy of Medicine are still bound by the code of ethics of the American Medical Association, that code having been adopted by the Academy, notwithstanding the late action of the Medical Society of the State of New York in superseding the code of the American Medical Association by a code of its own. We take it for granted that no Fellow of the Academy who has duly reflected upon the matter can entertain the slightest doubt as to the propriety of his conforming to the Academy's code so long as he retains his fellowship.

Certain collateral questions have been raised, however, and it is well that they should be considered by those who may take part in the controversy now in progress over the matter of codes. That they may be considered intelligently, it seems proper to ascertain, in the first place, precisely what stand the Academy has taken in regard to matters of ethics. The Academy of Medicine was incorporated June 23, 1851, by a special act of the Legislature. It therefore derives all its powers from the State. The following extracts from the act of incorporation, from supplementary acts passed subsequently, and from the constitution and by-laws, may be said to have some bearing on the questions to which we allude:

[Act of June 23, 1851.]

"Sec. 2. The said corporation shall have power to make and adopt a constitution and by-laws, rules and regulations for the admission, suspension, and expulsion of its members, and their government."

"Sec. 6. The Legislature may at any time alter or repeal this act."

[Act of June 4, 1853.]

"Sec. 5. The corporators hereby incorporated are authorized to appoint five delegates to represent them in the State Medical Society, with all the powers and privileges which delegates from the respective Medical Colleges of this State possess."

[Constitution.]

"Article II. The objects of the Academy shall be: . . . Second. The advancement of the character and honor of the Profession."

"Article III. 1. Each candidate for Resident Fellowship must have been a graduate or licentiate in medicine residing in this city and county, or in either of the counties of this State thereunto adjoining, for three years."

"Article VII. Section 1. Every Fellow shall be furnished with a duly authenticated certificate of fellowship, which may be revoked for cause; and in case of refusal to surrender the same, the Academy may publish such revocation in the public journals.

"Sec. 2. Any Fellow, having complied with the requirements of the Constitution and By-laws, may resign his fellowship, by presenting at a stated meeting a communication in writing to that effect.

"Sec. 3. No resignation shall be valid until accepted by the Academy."

"Article VIII. The Academy reserves the right of punishing violations of its regulations, or of its code of Medical Ethics, by reprimand, suspension, or expulsion, and will recognize no Fellow as a regular practitioner who has been expelled."

[By-Laws.]

"IX. Boards and Committees. . . Sec. 4. If an officer shall fail to discharge his duties to the satisfaction of the Academy, he may be dismissed from his office by a two-thirds vote; but no motion for dismissal shall be acted upon until the next stated meeting; prior to which meeting the Recording Secretary shall notify the alleged delinquent of such motion."

"XIII. Committee on Admissions. Section 1. Each candidate for Resident Fellowship . . . may be admitted at a meeting subsequent to his recommendation by the Committee."

"Sec. 3. . . and should this committee fail to report within the time specified upon any nomination submitted to them, any Fellow having made such a nomination may renew the same directly to the Academy, and a vote shall be taken upon it; in this case, however, the affirmative vote of four fifths of the Fellows present, as ascertained by ballot, shall be requisite to insure an admission; and on the question being put, it shall be distinctly stated that the nomination has not been approved by the committee."

"XIV. Committee on Medical Ethics. . . Sec. 5. All questions of ethics in other respects shall, as far as applicable, be adjudged in accordance with the Code of Ethics promulgated by the American Medical Association and adopted by the Academy."

"XXI. Signing the Constitution and By-Laws. Section 1. Every duly admitted Resident Fellow shall affix his signature to the Constitution and By-Laws within two months after his election; and in default thereof, said election shall be deemed void, unless a satisfactory excuse be given; nevertheless, he may be renominated and re-elected."

The bearing of some of the passages cited may be remote and contingent on points not at all certain to come up in this controversy, but, in view of the unexpected turn that the struggle has taken from time to time, it is well, we think, to bear them all in mind. The first deduction to be drawn from them is, that the Academy has full power to make and enforce such rules as it sees fit in regard to the admission, the government, the suspension, and the expulsion of members, provided, of course, those rules do not run counter to the laws of the State. It therefore had a perfect right to instruct its Committee on Admissions in the way it recently did instruct them by adopting Dr. Flint's resolutions. The question of the wisdom of that action is quite another matter.

Passing over the points that may be involved in several of our citations, we come to that article of the constitution in which the Academy reserves the right to punish violations of its regulations. Taking that article in connection with the fifth section of the fourteenth article of the by-laws, we seem to have the essentials of the Academy's requirements in the matter of ethics. We began by saying, in substance, that no reasonable person could doubt the duty of every Fellow of the Academy to govern his conduct in accordance with those requirements. But much more than this has been urged in some quarters. We have heard it gravely stated, for instance, not only that a Fellow of the Academy was bound to conform to its code of ethics so far as his individual acts were concerned, but that he was bound to uphold that code in every possible way—that, in fact, he was debarred from opposing the adoption or the maintenance of that code in other organizations, or even expressing an opinion unfavorable to it. It has been stated, too, that

every Fellow signed his name, at the time of joining the Academy, to an engagement of the nature of an oath, binding him to the course here defined.

Now let us look into the validity of these remarkable statements. For the moment we will put aside the matter of the alleged oath, and consider whether, on general principles, a member of an organization is for ever debarred from raising his voice against the rules which he finds in force in that organization. If such were the accepted principle, no rule or law of any sort would ever be repealed or amended, and our civilization would find itself so clogged that there would be no such thing as progress. Such a state of things would be intolerable. But it is quite unnecessary to pursue the theoretical argument in this direction, for the Academy has expressly provided for the repeal or amendment of any and every part of its constitution and by-laws. Manifestly the originators of this provision did not take pains to provide for measures that they intended to make impossible. But how is any repeal or amendment to be accomplished unless some one moves it, and how is such a motion to come about save as the result of opposition to the existing state of things? The *reductio ad absurdum* is obvious. And certainly whatever provisions for repeal or amendment apply to the constitution and by-laws as a whole, apply to every part of those documents, the ethical part included.

The next erroneous piece of doctrine inculcated is, that a Fellow of the Academy has no right to work against its code in another organization. The application is, that a Fellow of the Academy is debarred from opposing the re-enactment of the code of ethics of the American Medical Association, which is the Academy's code, in the State Medical Society. This is tantamount to saying that a Republican congressman from a Democratic State has no right to act against the Democratic party in Congress—a doctrine so obviously absurd that it would fail to gain the assent even of the most bigoted conclave of propagandists.

As to the alleged oath, or something of the nature of an oath, we may say, in the first place, that nothing of the sort is to be found in the published requirements for fellowship, and that, being therefore not necessary to be signed, if it has any existence at all, it has been interpolated surreptitiously, has been signed in ignorance if signed at all, and has not the slightest particle of validity.

The simple truth is, that, as a little reflection would teach any man of common sense, a Fellow of the Academy of Medicine, while unquestionably bound to abide by its rules in the matter of his personal conduct, is perfectly free to argue and vote against those rules in the Academy, and as free as any other member of the profession to oppose them in other organizations, or with the profession at large. Moreover, any opponent of the Academy's code, or of any of its rules, can sign its constitution and by-laws with a clear conscience and with perfect propriety, in case he should chance to be elected to fellowship, for by so doing he binds himself only as to his own observance of that code and those rules, and not by any means to be

fettered by them in the matter of his opinions or as to making all honorable efforts to spread those opinions or to secure their adoption in the Academy or elsewhere.

PUBLIC SENTIMENT TOWARD THE MEDICAL PROFESSION IN NEW HAMPSHIRE.

THE newspapers announce that one Dr. O. C. Gage, of New York, was arrested in Dover, N. H., last Saturday, charged by a medical student with practicing medicine without a license from a medical society in the State of New Hampshire. In itself the incident is not very remarkable, but the dispatch to the "World" concludes as follows: "It is believed that his arrest was instigated by the medical profession here, but they will not admit it." This seems to imply either that the state of public sentiment in the locality in question is such that the medical profession dare not take measures against illegal practice, or, having taken such measures, dare not acknowledge the fact. That ground should exist for either supposition is a disgrace to the people of Dover. Were the real attitude of the medical profession toward quackery unveiled to the public instead of being elaborately disguised with codes of ethics, a true understanding would soon be reached, and the profession would be supported rather than hampered by public opinion in its endeavors to put down quackery.

THE PROPOSED MEDICO-LEGAL JOURNAL.

It is announced that the publication of a quarterly journal of medical jurisprudence will soon be begun in New York. Although the expense of the venture is to be borne by a corporation to be organized for the purpose, the Medico-Legal Society has promised substantial encouragement to the scheme by subscribing for one hundred copies for exchange purposes, stipulating in return that its members shall have the benefit of a reduced rate on individual subscriptions.

We lately referred to the unsatisfactory way in which the society's proceedings, including much valuable matter, have hitherto been published, and we presume that the society, recognizing that fact, now counts upon seeing its proceedings appear in the new journal in a proper form. That this expectation may be realized, and that in all other respects the proposed journal may prove a substantial addition to the periodical literature of medicine, we earnestly hope. It is stated that the first number will appear shortly.

Most creditable journals devoted in great part to forensic medicine have been published in New York in the past, and the neurological journals of the present time contain a great deal of valuable matter relating to that branch of medical science. With these the new journal must compete, besides laboring under the disadvantages attaching to its restricted scope. To make it succeed, therefore, it is particularly necessary that it should be well managed. The Provisional Committee for shareholders, over whose signatures the announcement appears, contains several gentlemen whose connection with the undertaking augurs well for its success, however.

FRENCH JOURNALISM AND "AMERICAN QUACKERY."

In the "Union médicale" for April 17th we find brief abstracts of two articles that appeared in the "Therapeutic Gazette" for September, 1882. One of them is by Dr. Brewer, describing the physiological effects of manaca, and the other by Dr. Pepper, recounting a case of acute rheumatism in which the same drug was used with success after the failure of guaiacum, salicylic acid, bromide of potassium, and hypodermic injections of morphine. An individual who signs himself "L. D." adds this query: "*Serions-nous en présence d'un succédané de l'acide salicylique ou bien seulement d'une tentative d'american Quackery?*"

We would suggest to that exquisite satirist that, if he must bring in English phrases, it would be just as well to write them correctly, beginning the word American with a capital letter, and the word quackery with a small letter. We would also observe that the page which succeeds that in which he indulges in his elaborate sneer is wholly taken up with an article headed "*à propos de la suralimentation*," in which the author, one "M. le docteur de Servièrès, ancien interne des hôpitaux," sings the praises of *la leptone phosphatée (vin de Bayard)* in a disguised advertisement.

THE BOARD OF HEALTH AND ADULTERATED TEA.

An auction sale of a large quantity of tea was recently stopped by an injunction obtained at the instance of the New York Board of Health, to the great astonishment of the assembled brokers, as the newspapers remark. It seems that the so-called Ping-Suey teas were really of an inferior grade, adulterated, as the board's analysis declared, with deleterious mineral matter, so as to make them resemble what they were advertised to be.

It is impossible to overestimate the value of such a service as the board has rendered the community by this timely and summary action, assuming the facts to be as they are represented. Setting aside the cases of acute poisoning, but too commonly the result of spoiled or sophisticated articles of food, there can be little doubt that a great proportion of the dyspepsia and other chronic deterioration of health in civilized countries is due to the slow but continued injury done to the system by eating and drinking articles that are contaminated with foreign matter, as the result either of accident or of cupidity. In most instances, we believe, the retail dealer is innocent, or, at least, fails to appreciate the consequences that may come to those who consume the commodities in which he deals. The importer and the producer, while naturally feeling less responsibility, are under greater temptations to disguise the imperfections of their goods even by means that they must know are injurious, for they have a strict market to deal with. Such questionable transactions on their part are not likely to be discovered in the ordinary way until after widespread injury has had time to result; hence the necessity of constant watchfulness by sanitary organizations possessed of the resources necessary for the prompt detection of adulteration, and clothed with power to deal summarily with its perpetrators.

THE DIXMONT LUNATIC ASYLUM.

A JOINT committee appointed by the Legislature of the State of Pennsylvania to inquire into the matter of the alleged unsatisfactory management of the Hospital for the Insane at Dix-

mont have presented a majority and a minority report. In the former, the charges of maltreatment of patients, and of their detention after their recovery, are not substantiated, but it is urged that the State, which contributes largely to the support of the institution, ought to have the control of its management. The report also contains the excellent recommendation that the medical officer of an asylum for the insane ought to be relieved of the business administration of the establishment. We trust that the committee's suggestion may lead to legislative action in the direction alluded to. The day is not far distant when it will come to be recognized that the creditable management of such institutions can not be secured by placing it in the hands of a man who is expected to be an alienist, a financier, a landscape gardener, and a farmer.

THE MARYLAND MEDICAL JOURNAL.

THE first number of the weekly issue of the "Maryland Medical Journal," dated May 5th, being the first number of the tenth volume, has reached us, and it gives us pleasure to notice the continued excellence of the journal. In its general appearance it does not differ materially from the semi-monthly series. The editors, Dr. Thomas A. Ashby and Dr. Eugene F. Cordell, deserve great credit for the manner in which they have conducted it heretofore, and we have no doubt that they will carry it to a still higher level of prosperity and usefulness.

Proceedings of Societies.

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of February 17, 1883.

A PARTIAL STUDY OF THE POISON OF HELODERMA SUSPECTUM (COPE)—THE GILA MONSTER.—The following paper, by S. WEIR MITCHELL, M.D., and EDWARD T. REICHELT, M.D., was read: For some years past it has been known to naturalists that the Gila lizard of Arizona and Sonora was endowed with anterior deciduous grooved teeth, which communicated by ducts with large glands within the angle of the lower jaw. These arrangements naturally suggested a certain power of poisoning, as to which, however, the most conflicting accounts have reached and continue to reach us from Arizona. In many houses the sluggish creature shown to you was a pet of children, and seems to have been averse to using his weapons of offense. The occasional accidents from his bite were variously explained away; but still, among the Indians and some settlers, he enjoyed an evil reputation. Only within a week we have had two letters from Arizona, the one describing him as "more peaceful and harmless than a young missionary," and the other as being "worse than a whole apothecary shop." Nevertheless, both in France, and of late in London, specimens have bitten and promptly killed small animals.

It is worth while to mention more distinctly some of the evidence for and against the poisoning power of *Heloderma*. His bad name in Mexico is mentioned by Bocourt and Dumeril, but Sumichrast is more full in his statements.

This curious lizard is, he says, slow and embarrassed in his movements, and hides in the daylight, and especially in dry weather, to emerge at night and in wet seasons. He is said to smell ill, in fact, to be of a nauseating odor, and is described as slobbering forth a sticky, whitish saliva when irritated. The natives, says Sumichrast, hold him in the utmost terror, and consider him as more fatal than any serpent. When made to bite a fowl, it died in twelve hours, with bloody fluid exud-

ing from its mouth, the wound being of a purple tint. A cat bitten was very ill, but recovered, remaining thin and weak. The *Heloderma horridum* sent to London, to Sir John Lubbock, killed a frog in a few minutes, and a guinea-pig in three minutes.

Many years ago Dr. Irwin, U. S. A. ("Amer. Naturalist," Nov., 1882), experimented in New Mexico with the Gila monster, and concluded it to be harmless, while Mr. Horan, Superintendent of the National Museum, says he himself has been several times bitten without serious results. The following statement of Dr. Shufeldt (*ibid.*) adds a further difficulty in making up our estimate of the powers of *Heloderma*. The lizard he speaks of is the one we now exhibit. It was sent to the Smithsonian Institution by A. T. Burr, U. S. A., and is the H. suspectum of Cope.

On the 18th inst., in the company of Professor Gill, of the Smithsonian Institution, I examined for the first time Dr. Burr's specimen, then in a cage in the herpetological room. It was in capital health, and at first I handled it with great care, holding it in my left hand, examining special parts with my right. At the close of this examination I was about to return the fellow to his temporary quarters, when my left hand slipped slightly, and the now highly indignant and irritated *Heloderma* made a dart forward and seized my right thumb in his mouth, inflicting a severe lacerated wound, sinking the teeth in his upper maxilla to the very bone. He loosed his hold immediately, and I replaced him in his cage with far greater haste, perhaps, than I removed him from it.

By suction with my mouth, I drew out a little blood from the wound, but the bleeding soon ceased entirely, to be followed in a few moments by very severe shooting pains up my arm and down the corresponding side. The severity of these pains was so unexpected that, added to the nervous shock already experienced, no doubt, and a rapid swelling of the parts that now set in, caused me to become so faint as to fall, and Dr. Gill's study was reached with no little difficulty. The action of the skin was greatly increased, and the perspiration flowed profusely. A small quantity of whisky was administered. This is about a fair statement of the immediate symptoms; the same night the pain allowed of no rest, although the hand was kept in ice and laudanum; but the swelling was confined to this member alone, not passing beyond the wrist. Next morning this was considerably reduced, and further reduction was assisted by the use of a lead-water wash.

In a few days the wound healed kindly, and in all probability will leave no scar; all other symptoms subsided without treatment, beyond the wearing for forty-eight hours so much of a kid glove as covered the parts involved.

After the bite our specimen was dull and sluggish, simulating the torpidity of the venomous serpent after it has inflicted its deadly wound, but it soon resumed its usual action and appearance, crawling in rather an awkward manner about its cage.

The specimen shown has eaten once since we have had him, but the Gila monster is said to live on bird's eggs, and to eat daily of like food while in captivity.

The sluggish habits ascribed to *Heloderma* in general have been noticed in our specimen; but it is clear, from Dr. Shufeldt's accident, that, like the habitually inert *Crotalidæ*, this creature is capable of sudden, and, therefore, unexpected agility in attack.

As we shall have sent to us in the spring a number of *Helodermas*, we shall then be able to complete the study of the poison of these interesting lizards—the only members of the family of lizards as yet known to be poisonous. The subject is, however, too full of interest to delay the publication of our preliminary study, since, as far as it has gone, it is perfectly definite and satisfactory.

The Gila monster inhabits the dry hillides of Arizona, and is said to reach the length of three feet.

The specimen we exhibit is about fourteen inches long, and, from war or accident, had, when he reached us, lost all but two of his teeth, and as yet no new ones have taken their places. Without them he would certainly be as harmless as a rattlesnake deprived of his fangs; and as these teeth are very small and easily removed, their absence may account for some of the instances in which the lizard has bitten and done no grave harm.

Experiments made in the usual vague way, by allowing the lizard to bite animals, are obviously untrustworthy; so that it was thought best to use the saliva in known quantities. The fluid was obtained by provoking the animal to bite on a saucer-edge—which it was most indisposed to do. When once it had seized the saucer it was hard to pull it away, so powerful was the grip of the lizard's jaws. After a moment, a thin fluid like saliva dripped in small quantities from the lower jaw. It was slightly tinted with blood, due to the violence of the bite, and it had a faint and not unpleasant aromatic odor. The secretion thus collected from the mouth was distinctly alkaline, in contrast to serpent venoms, which are all alike acid.

Experiment I.—About four minims were diluted with one half cubic centimetre of water, and thrown into the breast muscles of a large, strong pigeon at 4.23 P. M. In three minutes the pigeon was rocking on its feet, and walking unsteadily. At the same time the respiration became rapid and short, and at the fifth minute feeble. At the sixth minute the bird fell in convulsions, with dilated pupils, and was dead before the end of the seventh minute.

The first contrast to the effects of venom was shown when the wound made by the hypodermic needle was examined. There was not the least trace of local action, such as is so characteristic of the bite of serpents, and especially of the *Crotalidæ*.

The muscles and nerves responded perfectly to weak induced currents, and to mechanical stimuli.

The heart was arrested in the fullest diastole, and was full of firm black clots. The intestines looked congested. The spine was not examined.

Experiment II.—Action on the Arterial Pressure.

Death.

In the foregoing experiment a full-grown etherized rabbit was used, and the left carotid being connected with the kymographion, one sixth of a grain of dry *Heloderma* venom, dissolved in one cc. of distilled water, was injected into the external jugular vein.

Experiment III.—The following experiment was made on a full-grown rabbit in which the pneumogastric nerves were cut, and in which the same dose and method of injection were used, the object being to determine if the above nerves were in any way connected with the changes in the circulation observed in the preceding experiments.

	.30	44	1.0	
	1.00	32	.3	
	1.30			
	1.35			Violent convulsions.

The animal died in convulsions with dilated pupils.

The results were identical with those obtained when the pneumogastrics were entire, so that the effect on the heart is direct, and not by inhibition through the pneumogastrics.

The results of the autopsy in both of the above experiments are identical, and may be summed up as follows:

Autopsy, made immediately after Death.—Heart arrested in diastole; heart does not react to induction currents; muscles everywhere respond to electric stimulation; motor nerves intact; cord unirritable, and will not respond to the strongest current produced by one large gravity cell, with Du Bois-Reymond's induction coil; bowels still irritable; peristaltic movements occur spontaneously; the intestines are natural in color, as are all other organs. After five minutes the heart began to contract, and was finally found in a systolic condition. The interior of the organ was full of black clots, especially the auricles, the left ventricle containing but a very small clot.

In order still further to determine the effect on the heart, the following experiments were made:

Experiment IV.—

hrs. min.

- 7.33. Pithed a frog and exposed the heart.
- .52. Heart beats 21 in 30 seconds.
- .52½. Placed a small portion of dried venom of *Heloderma* on the heart.
- .56. Heart beats 20 in 30 seconds.
- 8.05. " " 19 " "
- .18. " " 18 " "
- .30. " " 15 " "
- .43. " " 14 " "
- .55. " " 10 " "
- 9.30. " " ceased.

Experiment V.—

hrs. min.

- 8.05. Took two "cut-out" hearts of frogs, and placed them in a normal salt solution in separate vessels, just sufficient liquid being used to cover the hearts. On one heart was placed a small quantity of dried venom.
- .27. The poisoned heart beats more feebly than the other.
- .30. The poisoned heart beats still more feebly than the other, which is yet firm.
- .45. The poisoned heart stopped beating, the other beats firmly.
- .55. The poisoned heart stopped beating, the other beats firmly, but slower.

Experiment VI.—

hrs. min.

- 8.45. Exposed the hearts of two pithed frogs.
- 4.00. Placed on one some dried venom.
- .30. The poisoned heart beats are decidedly feebler than the other.
- .50. The poisoned heart beats more feebly; the unpoisoned heart beats firmly and apparently in a normal manner.
- 6.00. The poisoned heart beats very feebly and does not fill with blood. The normal heart beats firmly, and fills well with blood at each beat, making a striking contrast with the poisoned heart.

We may conclude that—

The poison of *Heloderma* causes no local injury.

That it arrests the heart in diastole, and that the organ afterward contracts slowly—possibly in rapid rigor mortis.

That the cardiac muscle loses its irritability to stimuli at the time it ceases to beat.

That the other muscles and the nerves respond readily to irritants.

That the spinal cord has its power annihilated abruptly, and refuses to respond to the most powerful electrical currents.

This interesting and virulent heart poison contrasts strongly with the venoms of serpents, since they give rise to local hemorrhages, and cause death chiefly through failure of the respiration, and not by the heart, unless given in overwhelming doses.

They lower muscle and nerve reactions, especially those of the respiratory apparatus, but do not, as a rule, cause extreme and abrupt loss of spinal power.

Finally, they give rise to a wide range of secondary pathological appearances, which are absent from *Heloderma* poisoning.

There remains on our minds no doubt as to the fact that the fluid which drips from the mouth of *Heloderma* when it bites is a very active poison. The present study is, however, limited in range, and we can not yet feel sure that the fluid in question comes from the glands now presumed, from their relation to the teeth, to be poisonous.

The briefest examination of the lizard's anatomy makes clear why it has been with reason suspected to be poisonous, and why it poisons with so much difficulty. Unless the teeth are entire, the poison abundant, and the teeth buried in the bitten flesh, so as to force it down into contact with the ducts where they open at the crown of the teeth, it is hard to see how even a drop of poison could be forced into the wounds. Yet it is certain that small animals may die from the bite, and this may be due to the extraordinary activity of the poison, and to the lizard's habit of tenaciously holding fast to what it bites, so as to allow time for a certain amount of absorption.

It is plain enough that a lizard as small as the one exhibited would be very unlikely to inflict a wound fatal to man; but it is possible that the larger animal—and it is said to reach a length of three feet—might prove a more efficient poisoner.

We are unwilling to drop the subject without a few words as to the nature of this poison.

The recent researches of Dr. Sternberg and Professor Gautier have shown that human saliva may kill a rabbit in twenty-four hours, and a pigeon in a few hours, if a quantity of saliva has been concentrated by heat and so used. Professor Gautier thinks the saliva and all venoms owe, at least, a part of their power to normal ptomaines or animal alkaloids, the products of putrefactive processes, and recalls to us the fact that most secretions are measurably poisonous.

The answer to these views we shall have to consider elsewhere, and at length, but it will be sufficient here to say that there is no resemblance between the symptoms caused by the known ptomaines and those produced by any of the venoms. When it was shown that healthy human saliva was competent to kill, it was natural enough to leap to the conclusion that the venoms were merely concentrated salivas. The analogy ends with the fact that both may cause death, but the one may kill in twenty seconds, and the other requires, at the least, many hours, while also it seems, as regards saliva, to be, in some degree, a question of the toxic activity of certain individuals, not all being so uncomfortably endowed as Dr. Sternberg himself.

NEW YORK ACADEMY OF MEDICINE.

A STATED meeting was held April 19, 1883, FORTYCE BARKER, M. D., LL. D., President, in the chair.

CRYSTALLINE ELATERIN.—Dr. Gaspar Griswold read a short paper on this subject, which will be found on page 514.

ANTEFLEXION OF THE UTERUS; ITS ETIOLOGY AND ASSOCIATED PATHOLOGICAL CONDITIONS.—Dr. W. Gill Wylie read a paper with this title.

The uterus, he remarked, is somewhat flexible and elastic, and when pressure is made on the fundus it bends, chiefly at a

point a little below its middle and opposite the os internum—not sharply, but in a parabolic curve. It is held suspended nearly in the center of the pelvic cavity, the axis of which crosses the long axis of the uterus just below its middle, the center of the cervix being somewhat posterior, and that of the fundus a little anterior to the axis of the pelvis. The top of the fundus is somewhat below the brim of the pelvis, and the cervix is below and behind the center of the pelvic cavity, the organ being held in position chiefly by the utero-sacral, the utero-vesical, and the broad or lateral ligaments, all of which are somewhat elastic, and permit considerable mobility of the uterus, especially upward and downward and backward and forward. The ligaments are attached to the uterus below its middle, except the broad ligaments, which cover it anteriorly and posteriorly and project from its sides, being attached to the pelvis in such a way as to give the uterus a forward inclination, and the round ligaments, which tend to prevent extreme backward displacement.

The vast quantity and disposition of connective or cellular tissue strengthen the pelvic floor, and assists in retaining the uterus in position, while they also permit free motion and power of adaptability of all the pelvic contents. The elastic contractility of the muscles and connective tissues together exerts a pressure which may be termed the vital musculo-connective-tissue pressure.

The Dynamics of the Pelvic Cavity, or the Influence of Forces in causing Antelexion.—Atmospheric pressure has little to do with keeping the pelvic organs in place. For this force to act as a retentive power by counteracting gravity, the vessel must be rigid and fixed above as well as on the sides, and impermeable to air. It helps to retain, by opposing gravity, only the liver and stomach, and these only when the diaphragm and ribs are made rigid by muscular contraction, as in holding the breath. It does not act on the pelvic organs in the same way, because the abdominal walls can be made rigid only by the downward action of the diaphragm, and thus the action is downward, and tends to drive out, instead of retaining, the organs in place by the removal of downward pressure. Gravity acts upon the contents of the pelvis as it does upon the semi-solid movable contents of a rigid cylinder with a flexible bottom and opening at the top into a flexible cylinder filled with an elastic mass, which falls and rises at all times with more or less force. What is it that prevents a normal uterus from bending forward at or above its middle when the person stands erect, or when the organ is pressed upon by the action of the diaphragm, the abdominal muscles, etc.? 1st. The firm and elastic nature of the tissues of the uterus permits motion, but tends to keep it in its normal shape. 2d. The forward inclination and slight anterior curvature of the normal uterus put it in the best possible position to enable it to withstand both continued and sudden waves of force from the action of the diaphragm and the abdominal muscles. In the erect posture, the pelvis of a normally formed woman is carried backward, so that a plumb-line dropped from the front of the first or second lumbar vertebra would pass through or in front of the os pubis. The erect posture curves the central part of the spine forward and carries the sacrum and coccyx backward, and thus renders the floor of the pelvis firmer than when the abdominal muscles are relaxed and the spine is straightened, as in the squatting and reclining postures. Postures which relax the abdominal walls also relax the floor of the pelvis, and those which render the abdominal walls tense tighten the pelvic floor. The wave of motion caused by the diaphragm passes downward through the mass of intestines, and, as they are attached posteriorly, is deflected forward against the abdominal wall, whence it is deflected backward and downward into the pelvis, and is much modified in force before

it reaches the uterus. If the long axis of the uterus is perpendicular to the plane of the pelvic brim, or somewhat anterior to the pelvic axis, the deflected and modified wave would strike and glide over the very top of the fundus, and spend its force on the floor of the pelvis. Blows upon or force produced by sudden contraction of the abdominal walls would pass backward and be received in the same way. Old men who have difficulty in urinating bend forward, not only to relax the perineum and pelvic floor, but to carry the abdominal wall backward, and, by voluntary contraction, cause a direct transmission of the wave from the diaphragm on to the bladder. For the same reason, when straining at stool, one leans very much forward in order to direct this force backward on the rectum.

Postures which tend to make the abdominal and pelvic cavities continuous may be injurious by bringing the uterus directly under the diaphragm. So long as the uterus retains its normal relations to the pelvic brim, it is in the best possible position to receive waves of force coming into the pelvis; for, as the pelvis is tilted up, the uterus is also lifted, and, when the brim of the pelvis is directly under the diaphragm, the long axis of the uterus is directed against the downward motion; besides, when sitting at ease, as the free borders of the ribs approach the pelvis, the abdominal wall relaxes and serves to dissipate the force of the diaphragm which is expended on the walls anterior to the pubes. As the spine is straightened, the pelvic floor is relaxed and the mobility of the organs much increased, and for this reason a patient can be best examined on her back with the legs flexed on a flat table. Work requiring rigidity of the body and tension of the abdominal muscles, such as running a sewing machine, with the body inclined forward, may be very injurious.

The Vital Musculo-Connective-Tissue Pressure.—By this is meant the sustaining power of the surrounding flexible, elastic, and adjustable tissues, which during life are filled with blood-fluid, etc., and are kept closely packed by the blood-pressure and the elastic contractility of the skin, muscles, fascia, and connective tissues of which the pelvic floor and abdominal walls are composed. This force is always more or less active, and, when the abdominal muscles are tense, is one of great power, not only keeping the organs in place, but regulating the pressure of the blood-vessels and the intestines. It is the removal of this power and the consequent disturbance to the circulation which produces the shock so often observed when the abdomen is opened. In the erect posture, the abdominal and perineal muscles are tense, and counteract the downward force of gravity by bringing their sustaining forces into full play. This influence is of great importance in the question of the dynamics of the pelvic cavity. In studying the influence of indirect pressure, the pelvis must be regarded as a cylinder, with an elastic top and bottom, filled with fluid, or a mass of tissue filled with blood, etc., and so elastic and mobile as to transmit force and be subject to the same laws which govern fluids. Therefore, when the floor of the pelvis is tense, force from above is transmitted more or less equally to all parts of the pelvis. While the uterus is surrounded by these elastic, adjustable tissues, it is sustained in the same way as a flexible sea-weed floating in water. In other words, the fundus is not so prone to fall forward as it would be out of the pelvis. The effects of falls and sudden efforts in producing antelexion have been exaggerated by advocates of the mechanical pathology of uterine displacements, who have overlooked this influence which greatly modifies the action of indirect forces on the pelvic organs.

Downward pressure, when very sudden, as in the act of coughing, would for a moment flex the uterus, but its natural elasticity and that of the surrounding tissues would cause it to rebound and assume its normal degree of curvature, and this

would be the case even though the pressure were continuous, as in lifting, straining, or lacing. General prolapse rather than antelexion is apt to be produced by downward pressure on the healthy uterus. Downward pressure from the abdominal muscles tends to produce, first, an exaggeration of the normal anterior curvature of the uterus; yet, as a rule, in the otherwise normal uterus, prolapse beyond a certain extent will produce retroversion, for, after a limited amount of descent, the cervix is forced forward by contact with the curved tissues behind it, and, unless it bends, which it is not likely to do if normal, the fundus must go backward. Backward displacements are of much greater importance, pathologically, than anterior displacements, because the degree of rotation of the uterine axis from its normal position is so much greater, the broadside of the organ receives downward pressure with more direct and greater force, the circulation is interfered with to a greater extent, and the uterus is abnormally fixed in the pelvis, its mobility is in a great measure lost, and the normal action of the vital musculo-connective-tissue pressure is much diminished.

Influence of the Bladder on the Position of the Uterus.—The bladder is a soft and very elastic organ, and, except at its base, free to move in all directions, so far as its attachments are concerned. Except when considerably distended, it has little or no influence in changing either the shape or position of the uterus. When distended, it carries the uterus backward, and tends to straighten out any anterior curvature. Partly filled, it makes up a part of the flexible, adjustable mass that surrounds and supports the fundus uteri. The elastic abdominal walls compensate by contraction or distension for any loss or gain in the pelvic contents.

The Influence of the Rectum on the Uterus.—The rectum is also a movable elastic body, which, when distended, pushes the cervix uteri to one side, and, if not habitually distended, has but little influence on a normal uterus. When habitually distended at its lower part, it greatly interferes with the normal circulation in the pelvis, and by distension and pressure stretches the pelvic fascia and uterine ligaments to such an extent that more or less prolapse of the uterus occurs, and, when the uterus is soft, flexes the cervix. An impacted rectum is nearly always associated with voluntary straining at stool, which, with the existing tendency to prolapse, will invariably induce antelexion, or more frequently retroversion and retroflexion.

The Point of the Greatest Curvature in Antelexion.—It is often difficult to determine the exact location of the greatest curvature in an antelexed uterus. As a rule, it is just about the os internum, because at this point the uterus is slightly smaller than at any other. The cervix and body unite at this situation; here the large blood-vessels enter and pass from the uterus and tend to weaken its walls, and just above the os internum the uterus is free, while the cervix below it is fixed by the utero-vesical and utero-sacral ligaments. When the vaginal part of the cervix is abnormally long, or large and soft, the flexion may be found at the vaginal junction. Flexion of the body or a caving in of one cornu is the result of local atrophy or extreme dilatation and thinning of the uterine walls.

Time of Making an Examination.—This should be carefully considered, for the amount of curvature will doubtless vary at different times—for instance, just before and just after menstruation. The best time would be during one or two weeks between the menses, when the uterus is usually quiet. If the uterus is an erectile organ, erotic excitement might tend to straighten it. If the function ascribed to the round ligaments by some authorities be correct, the uterus would be displaced forward during erection. Special conditions of the nervous system would probably have some effect on the shape of the uterus; as, for instance, when influenced by fear or intense mental excitement

it may be shriveled up, as the penis of a youth is when he is being examined the first time for venereal disease.

Variability of the Generative Organs.—The features of the external organs of generation vary in different races and individuals, and this normal variability characterizes the internal organs as well; and for this reason we can not lay down the law as to what will be the exact curve of the uterus, and, when the organ is found not to be of the exact size and shape of an absolutely perfectly formed uterus, it is not a sufficient reason for pronouncing it a case of pathological curvature to be treated by artificial support.

Frequency and Degree of Antelexion.—In a large percentage of the multiparous women whom the gynecologist examines, the uterus is abnormally flexed, but, in deciding what the normal curvature is, it must be remembered that nearly all of these women apply for examination because they have uterine disease, and the condition of their uteri can not fairly be used in estimating the normal standard. The angle made by the junction of two lines—drawn, one in the direction of the axis of the cervical canal, and the other in that of the canal of the body—might vary from an angle of 165° to 135° without being an abnormal curvature, but, if less than 135° , it may fairly be called abnormal.

Etiology.—The prevalence of imperfectly developed ante-flexed uteri in a community may be one of the first indications of race degeneration. The functions of the generative organs are not essential to the life of the individual. This full and proper development would seem to depend upon a surplus of vitality. In civilized communities the functions of these organs are kept under restraint; that is, women marry late in life, and, when this is the case for several generations, this enforced restraint (disease) of an organ may have a decided influence toward causing degeneration and atrophy. In a woman with a deformed pelvis, or in other respects showing imperfect development, we usually find an abnormally small ante-flexed uterus. Sometimes this is the case in strong and vigorous women. The condition of the general health has much influence on the development and position of the uterus. A rheumatic diathesis, or a tendency to catarrhal disease when the individual is exposed to cold or malarial poison, may induce endometritis, and finally lead to anterior displacement. Other causes may predispose to or induce anterior displacement, such as getting up too soon after labor, subinvolution of the uterus or its ligaments, uneven or unequal involution, specific elytritis extending to the endometrium, inflammation extending to the parametrium, especially pelvic peritonitis, imperfect development of the vagina, abnormal development of the cervix, habitual constipation, etc. Most of the local pain in this affection is due to congestion produced by the upright position, and to the general prolapse of all the pelvic organs.

Pathology.—In the congenital type, or in cases in which the flexion was acquired before maturity, the mucous lining at the point of curvature is usually pale and degenerated, with thick, hard, and fibrous, rather than muscular walls. In other cases the muscular tissue is scant, and the walls are composed of soft and flexible connective tissue, or indurated and giving evidence of old inflammation of the connective tissue. The os internum is usually contracted and inelastic, the contraction being due to organic rather than mechanical causes. If the cavity above is dilated, the os internum is found constricted.

Anteflexions may be divided into two classes—those which are usually termed congenital, and those in which the curvature takes place after full development. In the former, due to or complicated with imperfect development, both the fundus and cervix are frequently bent forward. The vaginal portion of the cervix is usually hard, abnormally small, flattened, and some-

what pointed, with the anterior lip crowded forward a little in advance of the posterior lip, giving the cervix a snout-like appearance.

In the latter class the cervix may not be much changed from the normal position and shape, while that part above the vaginal junction, or the part that is bent, is relatively small, flexible, and sometimes elongated so much that the round and small fundus can be moved about in any direction. When the cervix is bent forward in this class of cases, it is usually enlarged and hard, with more or less discoloration, due to imperfect circulation, and the flexion is more decided and fixed than in the simple cases when the cervix is not displaced.

[The Academy then proceeded to a consideration of certain resolutions introduced by Dr. Austin Flint, Jr., an account of which was given in our issue of April 28th, p. 462.]

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held February 20, 1883. Dr. CHARLES C. LEE, President, in the chair.

SOME OF THE EFFECTS OF NASAL POLYPI IN CHILDREN. —Dr. A. JACOBI narrated two cases, an account of which was given in the journal for April 7th, p. 376.

LARGE FIBROID TUMOR OF THE UTERUS UNACCOMPANIED BY SYMPTOMS. —Dr. B. F. DAWSON mentioned the case of a lady, thirty-two years of age, who recently consulted him, by the advice of Dr. J. H. Mennet, with regard to an enlargement in the abdomen that had attracted the notice of her friends only a few weeks previously. The patient was in excellent health, and had suffered no pain whatever; menstruation was perfectly normal. On examination, Dr. Dawson found a large multiple fibroid tumor of the uterus, occupying nearly the entire pelvic cavity, and pressing so tightly against the pubes that it was almost impossible to introduce the finger between. The case was somewhat unique in that the patient had been carrying a tumor of such large size without suffering any symptoms and in entire ignorance of its presence. The President had seen the case with him.

The PRESIDENT confirmed the statements made by Dr. Dawson with regard to this case, and stated that the probable explanation of the absence of symptoms was that the growth must have originated in the fundus, and developed upward and in directions not to cause such pressure upon the pelvic organs as would give rise to pain or other symptoms. By the time it had increased sufficiently in size and weight to occupy the pelvic cavity so fully as it did at present, the neighboring organs had become tolerant of its presence. He thought the case was an instructive one to gynecologists, in warning them against indiscriminately urging interference in cases of uterine growths, a tendency which, in the light of the brilliant success attending Battey's, Hegar's, and Tait's operations for the removal of the uterine appendages in cases of solid tumors of the uterus, was liable to occur for the next few years.

Dr. BACHE McE. EMMET replied to a question by Dr. Dawson with regard to what circumstances would justify an operation for the removal of such a tumor, that, in his opinion, an operation would not be justifiable except the patient's life was being rendered miserable and was jeopardized by the presence of the tumor.

DERMOID CYST OF BOTH OVARIES, AND CYSTIC TUMOR OF THE BROAD LIGAMENT. —Dr. W. T. LUSK presented two dermoid cysts, one of which had occupied the right and the other the left ovary, and also an unpunctured cyst of the right broad ligament, all removed from the same patient about two months ago. The patient made an excellent recovery.

Dr. GILLETTE stated that he could almost duplicate the speci-

men in one of its features. He had recently removed a cyst of the broad ligament in a girl about fourteen years old, when just such a cyst as the one shown was in progress of formation. It was secondary to the main cyst. The patient recovered.

In reply to a question by the President, Dr. H. D. NICOLL said that Dr. Thomas had operated on one patient with dermoid cyst of either ovary.

Dr. EMMET remarked that two years ago he reported a case of dermoid cyst of both ovaries.

QUARTERLY REPORT ON SURGERY.

No. XIV.

BY CHARLES B. KELSEY, M. D.,

SURGEON TO ST. PAUL'S INFIRMARY FOR DISEASES OF THE RECTUM.

ON THE TREATMENT OF CANCER OF THE RECTUM.—Mr. A. E. Barker ("Lancet," Feb. 24, Mar. 3, 1883) points out the different indications for treatment of cancer of the rectum as illustrated by a group of eight cases, in five of which he chose colotomy, in one excision, and in two no surgical interference.

The disease in seven out of the eight cases appeared, after careful manual examination and from the clinical history, to be the usual form of cancer met with in the rectum, which the author thinks is better described by the name of columnar epithelioma than adenoid. In one instance where excision was performed, the structure was proved by the microscope. In another the growth may have been encephaloid. In all but one the growth was seated fully three inches from the anus when first examined, and involved the whole circumference of the bowel; in one (in a male) it was limited to the postero-lateral aspect of the gut; in all the anus was free, and in none was there any glandular involvement or secondary deposit. In seven the family history was against heredity.

Blood in the motions was in four cases the first thing noticed, and was present, sooner or later, in all. Difficulty in defecation or diarrhœa was the next marked symptom, and after this bearing-down pain. Three of the patients suffered comparatively little from continuous pain, only complaining of a little during motions. Pain down the thighs was marked in two cases. In the more advanced cases diarrhœa (twenty passages daily) was a prominent feature.

The clinical factors upon which the author decided for or against operation were as follows: In Case 1 the growth had opened up the vagina, and the resulting incontinence of feces of the most revolting kind, together with the distress from the passage of the motions over the ulcerated surface of the cancer, fully justified the hope that an artificial anus in the loin would give relief. In Case 2 excision was justified by the malignancy of the growth, the suffering caused at each motion, and by its limitation and accessibility. In Cases 3 and 4 the growth was very chronic and bulky, and was causing obstruction alternating with profuse diarrhœa. Ulceration and perforation of the bowel above the stricture were, therefore, to be feared if a free exit for the motions was not immediately provided. In cases 5 and 6 the operation was almost entirely on account of severe pain, with diarrhœa, other troubles being less prominent. Morphine

produced constipation, and in this way rather aggravated than relieved the trouble. Finally, it was hoped that relief of the new growths from the irritation of defecation might retard their progress. In Case 7 the condition was not one that called for any active interference; and in Case 8, also, there was but little distress as yet, and, as the patient could command the best advice and any diet, the feces could be kept in a condition to pass readily through the contracted bowel, so that the patient, though seventy-seven years old, enjoyed very good health.

In five cases colotomy in the left flank was performed by Amussat's incision, in one excision. The wounds were in every instance guarded against septic contamination during the operation by frequent sponging with carbolic solution, especially after opening the gut. The subsequent dressing consisted of carbolic oil on lint, covered with a pad of salicylated wool. All the colotomy wounds healed rapidly, almost completely by first intention, except in one case, where, as the healing was rather too rapid, some of the fresh union was broken down to allow a little wider opening to the gut. Inflation of the bowel from the rectum was practiced in all the cases of colotomy, and the finding of the bowel was much facilitated thereby. In one case the peritonæum was wounded, but without bad consequences, as the wound was kept aseptic, and the opening of the bowel deferred until the fifth day after the latter had been stitched by its muscular coat only to the skin. Those cases did best in which the mucous membrane was most carefully sewn to the cut surface of the skin.

ON THE CURE OF ABSCESSSES ABOUT THE NECK WITHOUT CICA-TRIX OR OTHER DEFORMITY.—Mr. F. J. B. Quinlan ("Lancet," Jan. 20, 1883) has in two cases adopted an ingenious method of draining abscesses about the neck, which has resulted in a cure without deformity. It consists simply in passing a wire seton through the abscess cavity, and allowing the pus to escape gradually, and subsequently using compresses to facilitate the closure of the sac. The cicatrices left by the wire were in each case of about the size of the head of a pin, and scarcely noticeable. The needle is a thin, curved one, about three inches long, and the wire is fine and of silver.

The great point in the operation is to introduce the little silver seton immediately after suppuration has commenced, and while the pus is at least half an inch from the external surface. If it be allowed to come nearer, absorption of the areolar tissue will occur, and will leave a hollow over the site of the abscess. If nearer still, the true skin may be injured, and then there will be, in addition to the hollow, a red mark, which will last a long time. The needle is best introduced with a needle-holder, as otherwise it is difficult to pass it to sufficient depth. There should be no poulticing or application of stupes.

ROUGE'S OPERATION IN CASES OF DISEASE OF THE NASAL FOSSE.—Mr. Clement Lucas ("Lancet," Jan. 20, 1883), after some interesting data concerning Rouge's operation and Lawrence's modification of it, reports a case in which it was twice performed by himself on a patient suffering from syphilitic œzema. The operation was first described by Rouge in 1873 ("Nouvelle méthode pour le traitement chirurgical de l'œzème"), and consists in dissecting up the upper lip and the nose to allow of free access to the nasal fosse. This is in reality a modification of an operation previously suggested and practiced by Lawrence ("Med. Times and Gaz.," Nov. 8, 1862), which consists in turning up the nose alone, after separating it from the rest of the face by incisions, commencing externally at the lachrymal sac and extending down to the margin of the ala, dividing also the cartilages and the septum.

Although some objection has been made to these operations by the few surgeons who have practiced them, on account of the danger of the inhalation of blood, the author thinks well of

them both, but particularly of Rouge's, which allows of the free escape of blood anteriorly. The bleeding through the posterior nares, which is an element of danger, he controls by packing a large sponge, with a string attached, into the upper part of the pharynx. This latter precaution also prevents the patient from expelling blood and foul discharges into the face of the operator. The operation is particularly indicated for the removal of polypi and necrosed bone, and may even be undertaken as an exploratory procedure in cases of doubtful nature.

A CASE OF REDUCTION OF A DISLOCATION OF THE HIP BY INCISION INTO THE CAPSULAR LIGAMENT.—Dr. Polaillon ("Bull. gén. de thérapeutique," March 15, 1883) records a case of this exceedingly rare surgical procedure, and states that it is the third attempt of the kind on record, the first one being by Volkmann in 1876 ("Berlin. klin. Woch.," No. 25, p. 357, 1877), and the second by MacCormac in 1878. In both of these cases reduction failed, and the operation was completed by resection of the upper end of the femur, the patients recovering. In the author's case reduction was accomplished, but the patient died of gangrene. The case was an exceedingly poor one for surgical interference, the man being a drunkard, with the usual visceral changes caused by alcohol.

The operation was performed antiseptically. The cutaneous incision was 10 cm. long, starting from the anterior inferior spine. The muscles and fascia were incised to the same extent, thus exposing the joint. The great trochanter was found to be fixed against the cotyloid cavity, the upper border of which was masked by a thick layer of fibrous tissue, which extended from the upper border of the neck of the femur to the superior border of the cotyloid notch. This anterior thickened portion of the capsular ligament (the Y-ligament) was divided with the knife, and the finger could be passed between the neck of the femur and the cotyloid cavity, which was free. In spite of this division, an attempt at reduction by manipulation failed, and it was necessary to divide the muscles in front of the joint at their insertion. Further manipulation then brought the head of the bone out of the foramen ovale into a position over the cotyloid cavity, and thence the reduction was accomplished. No artery was wounded during the operation, which lasted three quarters of an hour, and the wound was dressed antiseptically. Four days after, the patient succumbed to a gangrenous inflammation of the deep femoral region. On autopsy, the head of the femur was found in the acetabulum. The author thinks that, in consideration of the patient's bad general condition, the death could not properly be attributed to the surgical interference, the operation being neither very long nor very severe.

Volkmann made in his case a long longitudinal incision, starting from the crest of the ilium and passing over the great trochanter. MacCormac made a Y-shaped incision, involving a great part of the femoral region.

ON THE TREATMENT OF CERTAIN FRACTURES OF THE LOWER END OF THE FEMUR.—Mr. F. Treves ("Brit. Med. Jour.," Feb. 17, 1883) records three important cases in which he has practiced division of the tendo Achillis as a primary step in the treatment of fracture of the lower end of the femur. It is in relation to this class of fractures that Bryant says: "In fractures of the lower third, above the condyles, where the gastrocnemii muscles tend to draw the lower fragments backward into the popliteal space, some surgeons prefer the use of the inclined plane, and, where the bones can not be otherwise kept in apposition, it is, probably, a sound practice. But what I believe will turn out to be a better one is the division of the tendo Achillis and the use of the long splint. . . . I have taught this for the last twelve years, but have had only one opportunity for testing its value."

The fractures referred to are generally either just above the

condyles, or are through the shaft just above that point. The fracture may be transverse or oblique; usually, however, of the latter variety; and the obliquity is apt to be extreme, with its general direction from behind downward and forward. The position of the upper fragment is practically unaffected, while the upper end of the lower fragment is drawn forcibly backward into the popliteal space by the action of the gastrocnemii muscles. The lower fragment is also drawn upward, and, from the twofold displacement, it follows that it may cross the axis of the upper fragment at a considerable angle while it lies behind that portion of bone. These fractures are often associated with secondary vertical ones through the condyles into the joint.

All fractures in this part are not attended by this deformity, and the treatment referred to is only recommended for those in which the lower fragment is forcibly drawn into the popliteal space by the gastrocnemii. It is obvious that these cases can not be treated in the ordinary way. Extension in the long axis of the limb merely increases the deformity by dragging upon the gastrocnemius and the lower fragment. In this way, with a long splint it would be possible for the limb to be put up apparently straight while the knee joint was in reality considerably flexed. It is useless to try and act upon the small lower fragments by pads and pressure, and, therefore, the long splint has been pretty generally abandoned in favor of the only other available treatment—viz., by some form of the double-inclined plane. By this the knee is bent and the large upper fragment is brought to the lower one; the parts can be well fixed to the splints, and the weight of the trunk is made use of as an extending force. In applying this treatment, the actual double-inclined plane is seldom made use of, but some modification of it, as MacIntyre's splint bent at the knee and slung from a cradle, Nathan Smith's anterior wire splint, Hodgson's suspension splint, and the like; in all of which the knee is bent, the parts below the fracture are practically fixed, and the weight of the body acts as an extending force. The objections to this form of treatment are found in the fact that the patient's body and the parts above the fracture are not fixed, and an undue freedom of motion in the upper fragment is possible; and also that the joint is fixed in a flexed position, and is liable to become ankylosed so. By section of the tendon, any deformity produced by the gastrocnemii muscles may be entirely removed, and the fracture may be treated with all those advantages which pertain to the long splint.

The author's three cases are related in full, and in two of them the local result was examined and noted post mortem.

DIGITAL EXPLORATION OF THE BLADDER.—Sir Henry Thompson ("Lancet," Feb. 10, 1883) states that during the past two years he has met with thirteen cases of obscure disease of the bladder in which he has thought it expedient to resort to digital exploration. In no less than six of them he has discovered and removed a vesical tumor of considerable size. He employs a limited incision in the perineum, carried to the membranous urethra only, and sufficing to enable him to carry the index finger to the neck of the bladder, after which, by supra-pubic pressure under complete anesthesia, the whole of the interior of the bladder may be examined by the finger.

In a previous paper he has stated that this incision has been frequently employed during two centuries for stricture, retention, etc., but that it had not been employed for the purpose of diagnosis as described above; and, moreover, that such an examination became possible only when, by anesthesia, the power was obtained of completely relaxing the patient's abdominal muscles. He also claims that the incision enables him to remove tumors, when found, which are not removable except by operation.

A full table of all the cases in which he has performed the incision, including those in which he has discovered and removed tumors, is given.

SEQUELÆ OF TRACHEOTOMY OCCURRING AFTER THE CLOSURE OF THE TRACHEAL WOUND.—Dr. Ross ("Edinburgh Med. Jour.," Mar., 1883) has met with a case in which tracheotomy was performed for the removal of a foreign body from the larynx of a child aged fifteen months, who twenty-two years later came under his care for a diaphragmatic obstruction of the trachea at the point of the previous incision; and this case has led him to go pretty thoroughly into the question of "What becomes of children who have been successfully tracheotomized?" It is known that cicatricial polypiform vegetations are a not infrequent cause of post-tracheotomy stenosis, and Dr. Gigon, of Angoulême, first called attention to this condition. The author gives the bibliography of fourteen such cases. Pathologically, they are similar to the granulation growths which sometimes cause serious respiratory difficulty on the removal of the cannula; but they do not manifest their presence till some days or weeks after the wound has healed. They are small tumors, varying in size from that of a hemp-seed to that of a pea, found growing from the inner surface of the tracheal cicatrix, very often from either angle, but more often from the inferior than the superior.

In addition to these two forms of stenosis, the author gives cases to prove that it is possible for laryngo-tracheal and nervous derangements, such as spasm of the glottis, to occur as late sequelæ of tracheotomy, and he believes that laryngeal phthisis and pulmonary emphysema may be directly referable to a previous tracheotomy. He quotes from Dr. Mougeot the remarkable statement that very few of the children successfully operated on for affections requiring the more or less prolonged retention of the cannula attain their majority. Military surgeons whom he had interrogated for over twenty years on this subject declared that they had never seen a conscript with a typical tracheotomy cicatrix, while between himself and a large number of professional brethren he could obtain knowledge of only six authentic cases of adults who had had the operation performed on them for croup in their childhood, and of these it was probable that two were reported twice. He also states that he had seen three patients who had been successfully operated on die before their twelfth year.

The article closes with hints as to the treatment of each of the sequelæ spoken of, and a valuable bibliography.

[Lack of space compels us to omit the publication of the bibliographical list appended to Dr. Kelsey's Report.]

Letters to the Editor.

REMARKS ON DR. FLINT, JR.'S, STATEMENT.

NEW YORK, May 5, 1883.

To the Editor of the New York Medical Journal:

SIR: The letter of Dr. Austin Flint, Jr., in your issue of to-day, apologizing for the action of the old-code party in packing the meeting of the New York Academy of Medicine on the evening of April 19th, requires one or two words of comment.

One of the fundamental virtues of the British House of Commons is the practice of giving notice of every proposed motion. A member of that body can not ask an important question without notice being duly posted. It is true that such "red tape," as some would call it, is at times embarrassing, and may seem to hinder "progress," but in the long run it does not do so, and rests on the firm basis of ingenuousness and fair play.

That ex-presidents of the Academy may be induced to sign a paper approving of a kind of parliamentary practice the opposite of that alluded to above, and the opposite of that which is right, only shows the extent to which attempts may be carried to defend what is wrong

in times of heated discussion. The history of partisanship shows nothing more clearly than the fact that you may get a large number of highly respectable gentlemen to defend a public act as virtuous from the perpetration of which they would individually turn away with instinctive abhorrence in cooler moments, or if acting separately.

The facts about the Academy meeting are, that a concerted effort was made to pack it, and to carry resolutions ruthlessly, without due notice. That fact is fixed in the history of the Academy, and no amount of signing of explanatory notes by highly respectable gentlemen will change it.

It is much to be regretted that in so-called deliberative bodies parliamentary jugglery, sleight of hand, and gymnastics may be resorted to to carry measures which could not be carried if time were allowed by majorities for minorities to be heard. When we reach a higher plane of culture we shall certainly show a more temperate spirit in advocating and propagating our opinions. The necessity for revising our ethics in the medical profession in this city and State is daily becoming more apparent.

Yours, faithfully,

C. R. AGNEW.

DR. AUSTIN FLINT, JR., AS A HUMORIST.

NEW YORK, May 5, 1883.

To the Editor of the New York Medical Journal:

SIR: It is refreshing to find that so sad a conflict as now exists in the profession, relative to the old and new codes, can be brightened by flashes of humor, as has been successfully demonstrated by Dr. Austin Flint, Jr., in his "Statement" which appears in your issue of this date.

In his first sentence he states: "I can scarcely imagine a provocation sufficient to induce me to enter into a personal controversy in the newspapers." In the "New York Herald" of to-day one may find the same "Statement," and what appears as an editorial preface, in which it is said that Dr. Flint, Jr., "has written a letter, under date of April 28th, to the editor of the 'New York Medical Journal,' which will appear in its columns this morning." The word "will" is not italicized in the "Herald."

In this communication to the "Herald" the following sentence is included in brackets: "Dr. Flint, Jr., here quotes from an interview with Dr. Fordyce Barker in the 'Herald' of April 21st." If this sentence was written by one of the editorial staff of the "New York Herald," instead of Dr. Flint, Jr., it was undoubtedly an unintentional error, instead of humor, as no report of an interview with me in relation to the old or new code, or any cognate subject, has ever been published in any newspaper.

But the full culmination of the humor of Dr. Flint, Jr., appears in the last sentence but one of his statement, in which he asks you to print from the "New York Herald" of April 21st the passages referred to above, "in order that the profession may form an opinion as to the justifiability of the personalities therein contained"; which you very properly do, including also its sensational headings.

The humor of the request and the reasons assigned are very much in the Artemas Ward vein, and probably were never equaled by him. "An opinion as to the justifiability of the personalities therein contained" was just what the writer of the "Statement" did not wish, or he would have referred to the report of my speech published in your issue of the same date, the accuracy of which report every one who heard the speech will vouch for, and for which I will accept the responsibility, and in which the reasons for the so-called personalities are clearly and distinctly given—instead of asking that a newspaper report, published seven days before, be reprinted, which I never saw before its republication, and which does not contain a single sentence correctly reported which I uttered, or give the slightest indication of the purpose and motive of my remarks.

Yours, truly,

FORDYCE BARKER.

* * * As our issue of the 5th inst. was really published on the 4th, we presume that the "Herald" simply followed the ordinary custom of courtesy in using the word "will" in connection with an extract from our columns.

ETHICS AMONG LAWYERS.

NEW YORK, May 7, 1883.

To the Editor of the New York Medical Journal:

SIR: Conversing the other day with a friend of mine, a lawyer of prominence and influence, he remarked that he had been recently consulted by a widow lady of some little means as to an extremely important legal matter which she had in hand. I say consulted, but it never came to that, for the business was already in the hands of another lawyer, whom my friend believed to be a charlatan, and with whom he therefore very properly refused to come into contact. He would not listen to the lady's story, nor hear a word from her about the matter, unless she would first dismiss her former adviser. She protested that she only wanted to know whether the course which was being pursued was the right one. If it was, she was content to let her lawyer go on as he was doing; if not, she desired that a different line of action should be indicated, and for this information she was willing to pay an appropriate fee. She had confidence in her lawyer in the main, as he had done a great deal of business for her in the past to her entire satisfaction, but she felt some solicitude as to the correctness of his judgment in this particular case. My friend, however, with a noble devotion to principle, maintained his ground, and the result was exactly what he foresaw—the lady's fortune was completely wrecked through her lawyer's incompetency.

As he concluded his narrative I could not refrain from congratulating him on the dignity of the course he had pursued, and remarking that he had done as a lawyer simply what our grand old code of ethics enjoins upon us as medical men. It would be well if some of our brethren at the present moment would learn a lesson from this gentleman of what we owe to the profession and to ourselves.

Very truly yours,

ROXBORO.

Miscellany.

THE GERMICIDE VALUE OF CERTAIN THERAPEUTIC AGENTS.—In the "American Journal of the Medical Sciences" for April, 1883, Dr. G. M. Sternberg relates a long series of experimental studies as to the germicide value of certain therapeutic agents on various forms of bacterial organisms. In his experiments on the micrococcus of gonorrhoeal pus, he found that, in general, those reagents which destroyed the vitality of the micrococcus from pus were destructive of other organisms of the same class; and that their relative value as germicides was not changed when a different micro-organism was used as the test of this value. Moreover, the reagents which were found to be practically valueless as germicides in the first series of experiments—e. g., ferric sulphate, sodium sulphite and hyposulphite, boric acid, etc.—proved to be equally without value when the test was extended to other micro-organisms of the same class. But the reagents found to possess decided germicide power have, in some cases, a different value for different organisms. In other words, the vital resistance of different bacterial organisms to the reagents in question is not the same in all cases. Nevertheless, the comparative germicide value of the reagents tested is the same for the several test-organisms, and, allowing certain limits for specific peculiarities, it is safe to generalize from the experimental data obtained in the practical use of these reagents as disinfectants. But it must be remembered that the resisting power of reproductive spores is far greater than that of bacterial organisms in active growth (multiplication by fission), and the data obtained for the latter can not be extended to include the former. The antiseptic value of the reagents tested depends upon their power to prevent the multiplication of putrefactive bacteria, and this is not necessarily connected with germicide potency.

DEATHS DURING THE ADMINISTRATION OF ANÆSTHETICS.—In a paper entitled "Remarks on the Death-rate of Anæsthesia, with an Account of Six Fatal Cases," published in a recent number of the "British Medical Journal," Mr. W. Roger Williams, F. R. C. S., remarks in con-

clusion: "I have observed that those who administer anæsthetics, too often, do so without any fixed principles to guide them. This is regrettable, because, as many of these cases show, the fundamental laws of the anæsthetic art can not be disregarded without entailing a deplorable sacrifice of life. I will here endeavor to state, in the briefest manner possible, the most important practical inferences from them. With regard to chloroform, then, subject to the attainment of the object in view, too much air can not be given during its administration; and, with regard to ether, too little air can not be given during its administration. From this, it follows that a long time is required to induce anæsthesia by chloroform; but, to produce the same result with ether, a short time is sufficient. Now, by a long time I mean about a quarter of an hour, and by a short time about five minutes. Surgeons are not unfrequently to blame in this respect. How often one has heard it said to the chloroformist—'Be as quick as you can; I want to commence the operation in five minutes.' In my opinion, this is equivalent to saying—'Kill at least one per cent. of my patients. Those kind of inhalers are the best which most facilitate the fulfilment of these requirements. For giving chloroform, one with a wire framework, having a diaphragm of flannel, or some similar material stretched over the top of it, on which to evaporate the anæsthetic, but open at the sides, would be very good; but a piece of lint, or the corner of a towel, properly used, would do as well. A graduated drop-bottle is necessary in any case, as only a small quantity of chloroform should be poured on at a time, which requires to be frequently renewed. For the administration of ether, Ormsby's inhaler seems to me to be the best; it was designed to fulfill the requirements just mentioned, and I have found it answer admirably. There is only one other point I will now mention, and that is the importance of watching the respirations during the process. To do so properly, of course the epigastrium must be uncovered. It is of much greater value than feeling the pulse, since, when the latter stops, there is, as a rule, an end of the patient. Mr. Lister has very ably insisted on this. However, I have found it generally neglected at King's College."

IODINE AS A STOMACHIC SEDATIVE.—The employment of iodine for the relief of the vomiting of pregnancy has been somewhat in vogue for a number of years. While the success attending its use has been pointed out with more or less enthusiasm, its exact value has never been established. Dr. T. T. Gaunt ("American Journal of the Medical Sciences," April, 1883) has for a number of years been employing the compound tincture of iodine in drop doses in nearly all forms of emesis, and reports thirteen cases of the most varied character, in all of which vomiting was promptly arrested by the use of this drug.

KAIRINE.—The "College and Clinical Record" remarks that kairine is a recent product of the laboratory which promises to be a useful antipretic, and, it is stated, is unaccompanied by the slightest tendency to produce local irritation. It is proposed as a substitute for chinoline, itself a substitute for quinine. Fischer and Wilhelm König, of Munich University, assisted by Professor Fiehn, of Erlangen, have found that those hydrides of chinoline in which the nitrogen atom is in direct combination with the carbon atom of a methyl group or of another alcohol radical, all possess, more or less, the properties above mentioned as pertaining to kairine. Kairine is the name given by the authors to oxychinoline methylhydride. Kairine hydrochlorate forms a light, grayish-yellow crystalline powder. It is soluble in water, and has a bitter, aromatic taste.

THE ACTION OF CHLORAL, OPIUM, AND BROMIDE OF POTASSIUM.—In an article in the "British Medical Journal," embracing a recital of experimental investigations, Dr. Sidney Ringer and Dr. Harrington Sainsbury make the following important observations on certain well-known drugs, after discussing the physiological effects of the agents mentioned in the title of their paper: "Clinically, the dangers of bromide of potassium and of chloral have been recognized; and thus in our text-books we find the statements that the presence of grave adynamic symptoms contraindicate chloral and bromide of potassium. Opium, on the other hand, in such adynamic states, frequently appears to lend actual support. The results of definite experiment we find to accord with the results of clinical experience; and the value of the former

lies in that they confirm, and by their definiteness must tend to enforce, the teachings of the latter. The choice of a drug is, however, no simple matter; an advantage here may be outbalanced by a disadvantage there; and practical men may object that they would gladly give opium, but that the disordered stomach, blunted appetite, inactive liver, and torpid intestines more than outweigh the advantages of opium administration. This clearly is a matter for consideration in the individual case under treatment; and the decision will have to be according as one or other element—asthenia, or derangement of the digestive, etc., powers—is most to be feared. These objections to opium on the one hand, and chloral and bromide of potassium on the other hand, raise the question as to whether, in very many cases, a drug, at present rather extensively used, especially in America—viz., bromide of sodium—might not with advantage be substituted in their place. The salts of sodium generally contrast very markedly with those of potassium; for the chlorides, bromides, and iodides of these two metals, the lowest figure would represent the potassium as ten times as active as the sodium. These precise numbers refer to action on the ventricle of the frog's heart (see "Medico-Chirurgical Transactions," vol. lxx, concerning the action of the salts of potash, soda, and ammonia on the frog's heart), but on all hands the evidence is forthcoming that, while salts of potassium are very poisonous, those of sodium are very slightly so. One of the marked points of contrast between the two sets of salts is to be found in respect of inhibition; potassium salts inhibit the frog's ventricle strongly, sodium salts scarcely at all. Here however, we are considering drugs as to their cardiac effect; and, in respect of this, sodium bromide would rank far ahead of bromide of potassium, chloral, or opium, as to innocuousness. The objections holding for opium would not apply here, for sodium salts are generally very little disturbing to the tissues. With these advantages the general verdict of clinical experience is to the efficacy of bromide of sodium as a hypnotic, and, indeed, as a substitute for bromide of potassium; and, should this position be maintained, it is clear that bromide of sodium will be in very many cases the sedative above all others to be selected."

THE MECHANICAL THEORY OF STERILITY.—In one of his Gulstonian lectures on sterility ("British Medical Journal"), Dr. Matthews Duncan, of London, says: "The very zeal with which the mechanical theory of sterility has been fostered, and its treatment in many ways pursued, has led to its present decadence, and there is now increased attention paid to other departments of fertility than conception. Especially and justly, the difficulties of naturally starting and healthily continuing pregnancy are brought prominently into view. The mechanical obstruction theory has begun to shrivel, because of the impression produced by the enormous, though inexact, ascertained, proportion of the failures of the attempts to cure founded on it. Even the ignorant sterile women could see that, if the theory of causation were true, there was an easy and plain theory of cure; and they could also see that the failure of the so-called cure was prejudicial to, if not destructive of, the theory. The importance of the difficulties of pregnancy now brought into prominence will, on account of its great reconditeness, be received with no enthusiasm, such as welcomed the obstruction theory; and the physicians who entertain it can offer no such brilliant prospects of cure to their confiding patients. It is, however, a decided step of progress in a subject of great practical importance."

ESCAPE OF BLOOD FROM THE LACHRYMAL DUCT DURING EPISTAXIS.—Mr. D. Hoadley Gabb, M. R. C. S., of Hastings, writes to the "British Medical Journal": "Mr. S., aged fifty, with mitral disease and albuminuria, sat out one of our recent sunny days and caught a chill, which culminated in an attack of bronchitis and a relaxed state of the fauces and uvula, producing severe spasmodic cough; during one of these paroxysms, epistaxis, from the right nostril especially, came on rather profusely, and I was sent for. There was no difficulty in arresting it by plugging the anterior nares with dry lint. In two or three hours, after a severe cough, the hæmorrhage returned, and a messenger was sent for me, saying the bleeding had come back, and was running out of his nose and eyes; and so I found that the blood had welled up through the right lachrymal duct and was suffusing his eye, so that he

was constantly obliged to wipe it, and the handkerchief was pretty well stained with the blood, and the discharge only ceased when the nose left off. I have never met with the phenomenon before, neither have others to whom I have mentioned it; and so, I think, perhaps it is worth recording."

RENAL INADEQUACY.—In an address on this subject recently delivered before the Metropolitan Counties Branch of the British Medical Association, and published in the "British Medical Journal," Dr. Andrew Clark stated: "There is a certain state of the kidney in which, without any alteration of structure that the eye can detect, it can, nevertheless, not produce a perfectly healthy urine. It is a urine low in density and deficient in solid constituent, principally in urea and its congeners. I call this state renal inadequacy. You may say, 'It seems scarcely wise to introduce a name like that, when probably it is nothing less than an early stage of Bright's disease. Why bring in another name?' I will not say that it is not an early stage of Bright's disease; I do not know. I think it need not necessarily be; but I shall assume that it is, perhaps, a very early stage of Bright's disease. I nevertheless think it of practical value—and we who are here to-night are practical men—to recognize by a distinct name a state which may remain as it is during the whole period of life, which is nevertheless capable of removal, and which, if unnoticed, may lead to serious injury to the patient. Let me explain. The people who have this renal inadequacy are characterized by three things particularly. First and foremost, they are characterized by a curious inability properly to repair damages done to them either by accident or by disease. I have no doubt you as well as I have often been puzzled to know why, in particular cases, they could not repair a common accident; or why, in a disease such as pneumonia, the exuded stuff was not melted and speedily swept away; why a man who had met with some trifling accident in the wrist or shoulder remained suffering from it. Then, they not only repair damages of this kind slowly, but they are peculiarly vulnerable. They are a people, as a rule, who are always catching cold, and who, when they catch cold, come within the category of the first characteristic—namely, that they do not get rid of the cold. They are the people who, without apparent reason, and without other existing disease, get pneumonias, pleurisies, pericarditis, and the like. Then, thirdly—and, I think, almost the most important thing to be noticed about these cases—you can never be sure of the result of the performance of an ordinary surgical operation upon them. It is this class of people, as I had the opportunity a few years ago, in London, of discovering, that die from a simple operation by hæmorrhage. It is this class of people who have an abscess opened and immediately become what is called pyemic. It is this class of people who, without his being able to explain it, attracted the notice of that distinguished surgeon Sir James Paget. Some years ago he said: 'Whenever I find a man in ill-health, without definite cause for the ill-health, I feel sure that my chances of success in operating upon him are diminished by at least one half.'

NITRITE OF AMYL AND NITRO-GLYCERIN IN URÆMIC ASTHMA.—Dr. Sheen, of Cardiff, furnishes the "British Medical Journal" with brief notes illustrating the value of nitrite of amyl and nitro-glycerin in one of the sudden and distressing, though perhaps rare, phases of chronic Bright's disease—viz., uræmic asthma. "Nitrite of amyl," he continues, "acting probably through the vaso-motor nerves, relaxes the arterioles, and thus reduces blood pressure. As it is very volatile, on the score of economy and convenience, I always carry some of Martindale's capsules in my bag, and these are very handy for immediate use. Nitro-glycerin is said to have much the same action as nitrite of amyl, and, according to Dr. Mabomed, its great superiority over amyl lies in its gradual and more lasting effect, and the more convenient manner of prescribing it, and it can be taken regularly two or three times a day, or oftener, one minim of a one-per-cent. alcoholic solution being the usual commencing dose. It is also made up in chocolate tablets, each containing one one-hundredth part of a minim; but its action, when given in this form, is not so rapid as that of the alcoholic solution."

THE BRITISH MEDICAL ASSOCIATION.—The Fifty-first Annual Meeting will be held at Liverpool, on Tuesday, Wednesday, Thursday, and Friday, July 31, August 1, 2, and 3, 1883. *President:* WILLIAM STRANGE,

M. D., Senior Physician to the General Infirmary, Worcester. *President-elect*: A. T. H. WATERS, M. D., F. R. C. P., Physician to the Royal Infirmary, and Professor of Medicine in University College, Liverpool. An Address in Surgery will be delivered by REGINALD HARRISON, F. R. C. S., Surgeon to the Royal Infirmary, Liverpool. An Address in Pathology will be delivered by C. CREIGHTON, M. D., formerly Demonstrator of Anatomy, University, Cambridge.

The business of the Annual Meeting will be conducted in ten sections. **SECTION A. MEDICINE.**—*President*: John Cameron, M. D. *Secretaries*: Thomas R. Glynn, M. D.; Frederick T. Roberts, M. D. *Secretaries*: Richard Caton, M. D., 18a Abercromby Square, Liverpool; Byrom Bramwell, M. D., 23 Drumsheugh Gardens, Edinburgh. **SECTION B. SURGERY.**—*President*: Edward R. Bickersteth, F. R. C. S. *Vice-Presidents*: W. Hargreaves Manifold, M. R. C. S.; W. Mitchell Banks, F. R. C. S. *Secretaries*: Rushton Parker, M. B., F. R. C. S., 61 Rodney Street, Liverpool; Edmund Owen, M. B., F. R. C. S., 49 Seymour Street, Portman Square, W. **SECTION C. OBSTETRIC MEDICINE.**—*President*: W. M. Graily Hewitt, M. D. *Vice-Presidents*: John Wallace, M. D.; David Lloyd Roberts, M. D. *Secretaries*: John E. Burton, L. R. C. P., 64 Rodney Street, Liverpool; W. C. Grigg, M. D., 6 Curzon Street, Mayfair, W. **SECTION D. PUBLIC MEDICINE.**—*President*: T. P. Teale, M. B., F. R. C. S. *Vice-Presidents*: William Carter, M. D.; W. Honner Fitz-Patrick, M. D. *Secretaries*: F. Pollard, M. D., 52 Rodney Street, Liverpool; George Goldie, M. D., 123 Hyde Park Road, Leeds. **SECTION E. ANATOMY AND PHYSIOLOGY.**—*President*: Professor E. A. Schafer, F. R. S. *Vice-Presidents*: William Stirling, M. D.; Richard Norris, M. D. *Secretaries*: James Barr, M. D., 1 St. Domingo Grove, Everton, Liverpool; A. W. Mayo Robson, F. R. C. S., Hillary Place, Leeds. **SECTION F. PATHOLOGY.**—*President*: T. H. Green, M. D. *Vice-Presidents*: E. H. Dickinson, M. D.; Joseph Coats, M. D. *Secretaries*: Frank Thos. Paul, F. R. C. S., 44 Rodney Street, Liverpool; James F. Goodhart, M. D., 27 Weymouth Street, W. **SECTION G. PSYCHOLOGY.**—*President*: T. L. Rogers, M. D. *Vice-Presidents*: G. H. Savage, M. D.; D. Yellowlees, M. D. *Secretaries*: G. F. Shuttleworth, M. D., Royal Albert Asylum, Lancaster; W. Julius Mickle, M. D., Grove Hall Asylum, Bow, E. **SECTION H. OPHTHALMOLOGY.**—*President*: T. Shadford Walker, M. R. C. S. *Vice-Presidents*: E. Nettleship, F. R. C. S.; C. E. Fitzgerald, M. D. *Secretaries*: E. A. Browne, M. R. C. S., 86 Bedford Street, Liverpool; C. E. Glascoat, M. D., 23 St. John Street, Manchester. **SECTION I. DISEASES OF CHILDREN.**—*President*: Samuel Jones Gee, M. D. *Vice-Presidents*: M. G. B. Oxley, M. D.; T. R. Jessop, F. R. C. S. *Secretaries*: H. G. Ravdon, M. D., 42 Rodney Street, Liverpool; H. Ashby, M. D., 13 St. John Street, Manchester. **SECTION J. OTOTOLOGY.**—*President*: G. P. Field, M. R. C. S. *Vice-Presidents*: Edward Woakes, M. D.; C. Warden, M. D. *Secretaries*: Thos. Barr, M. D., 16 Albany Place, Sauchiehall Street, Glasgow; R. Williams, L. R. C. P., 82 Rodney Street, Liverpool.

Honorary Local Secretary: Alexander Davidson, M. D., 2 Gambier Terrace, Liverpool. *Honorary Treasurer*: W. Mitchell Banks, F. R. C. S., 28 Rodney Street, Liverpool.

The following order of exercises is announced: **TUESDAY, July 31, 1883.** 10.30 A. M.—Church Service at Pro-Cathedral. Sermon by Bishop of Liverpool. 12 M.—Meeting of Committee Council. 12.30 P. M.—Meeting of the Council, 1882-'83. 3 P. M.—First General Meeting: Report of Council and other business. Adjourn at 5 P. M. 8.15 P. M.—Adjourned General Meeting: President's Address, and any business adjourned from meeting at 8 o'clock. **WEDNESDAY, August 1, 1883.** 9.30 A. M.—Meeting of Council, 1883-'84. 11 A. M.—Second General Meeting. Address in Surgery. 1.30 to 5 P. M.—Sectional Meetings. 9 P. M.—*Noirée* in the suite of rooms forming the Arts Gallery, the Picton Reading-Room, and the Free Library, by the President and Local Committee. To this, ladies will be invited. **THURSDAY, August 2, 1883.** 9 A. M.—Meeting of Committee of Council. 10 A. M.—Third General Meeting. Sectional Meetings. Adjourn at 1 P. M. 2 to 5 P. M.—Sectional Meetings. 6.30 P. M.—Public Dinner in the Philharmonic Hall. **FRIDAY, August 3, 1883.** 10 A. M.—Fourth General Meeting. Address in Pathology. Sectional Meetings. 2 P. M.—Concluding General Meeting. 9 P. M.—*Noirée* by the Mayor of Liverpool, at the Town Hall. To this, ladies will be invited. **SATURDAY, August 4, 1883.**—Excursions.

THE MEDICAL ASSOCIATION OF CENTRAL NEW YORK.—The Sixteenth Annual Meeting will be held at Association Hall, Nos. 53 and 57 East Genesee Street, Syracuse, Tuesday, May 15, 1883, at ten o'clock A. M. A resolution was adopted at the last meeting requesting the secretaries of the county societies in affiliation with the association to forward the names of deceased members in their respective counties to the secretary, on or before the 1st of May and 1st of November, in each year; also that members intending to present papers at the meeting should report their titles to the secretary instead of to the president, as heretofore. Among other subjects of interest, Dr. A. Clifford Mercer will exhibit specimens of bacilli tuberculosis under the microscope.

THE COLLEGE OF PHYSICIANS AND SURGEONS.—The annual commencement exercises will be held at Steinway Hall on Tuesday, the 14th inst., at 3.30 P. M. The Rev. Noah Porter, D. D., President of Yale College, will deliver the address to the graduating class.

THE OBSTETRICAL SOCIETY OF LONDON.—For the information of those of our readers who may visit London during the coming summer, we publish the announcement that the Library of the Obstetrical Society has been removed from No. 291 Regent Street to No. 54 Berners Street, W. The hours of attendance are: Monday to Friday, 1.30 to 6 P. M.; Saturday, 9 to 11 A. M.

THE FREEDMEN'S HOSPITAL.—It seems that certain allegations, lately made public, that the financial affairs of the Freedmen's Hospital at Washington had been managed discreditably, have no adequate foundation in fact. If there were any technical irregularities—and even of this there is no convincing proof—they were such as could not readily have been avoided.

THE NEW PROFESSOR OF SURGERY IN BELLEVUE HOSPITAL MEDICAL COLLEGE.—The "Lancet" speaks as follows of Dr. Frederic S. Dennis, the new Professor of Surgery: "It will be readily believed that, since the resignation of his chair, in December last, by the lamented Van Buren, the question of his successor has been one of the first interest in New York. This honor has fallen on Dr. F. S. Dennis. Though Professor Dennis should think himself fortunate in being elected at a comparatively early age to succeed such a man in such a chair, we have no doubt that he will justify his election. Professor Dennis is, as Van Buren was, a graduate of Yale College. He was a favorite pupil, and at one time an assistant, of Dr. James R. Wood. He was two years in Bellevue Hospital, and in the year of his graduation took the first prize and gained the highest mark in the competitive examination. Dr. Dennis was not content with learning the surgery of his own country, but studied for two years under Langenbeck, and enjoyed very intimate and pleasant relations with the illustrious surgeon of Berlin. We are glad to add that Dr. Dennis spent some time in studying surgery in London, and became a member of the English College of Surgeons. For the last few years Dr. Dennis has been on the staff of Bellevue Hospital, and has done good work as a teacher of anatomy and surgery."

THE TEWKSBURY ALMSHOUSE INQUIRY.—With whatever credit he might have gained with the decent part of the community by unveiling the real abuses that have doubtless prevailed in the management of the Almshouse at Tewksbury, Mass., Governor Butler has contrived to mingle abundant evidence that he is in great part catering to the vulgar appetite for sensational details. For instance, we hear a good deal just now of the "tanning of human skin" for students at the Harvard Medical School, which revolting practice has, of course, nothing to do with the questions at issue.

THE LUNATIC ASYLUM AT NEWARK.—Certain allegations having been made against the managers of the Essex County Lunatic Asylum, at Newark, N. J., embracing charges of maltreatment of patients, and the like, the Board of Freeholders are understood to have declined to make an investigation in regard to them. It now seems likely that the Grand Jury will take the matter up, and more public scandal is to be looked for than if the Freeholders had resolutely gone to work at it in the first instance, however little ground there may have appeared to them to be for such a course.

PUBLIC HEALTH IN CONNECTICUT.—According to a recent report by the secretary of the Connecticut State Board of Health, Dr. C. W. Chamberlain, of Hartford, pneumonia and other acute pulmonary diseases were still playing a leading part in the mortality lists; the prevalence of scarlet fever had declined, although, in common with measles and whooping-cough, it was prevailing rather more than diphtheria; erysipelas was more common than usual; malarial affections were much less frequent than during the preceding year; and "winter diarrhoea" was disappearing.

PRECAUTIONS AGAINST YELLOW FEVER ON THE MEXICAN FRONTIER.—Recent accounts from Texas are to the effect that considerable anxiety is felt there as to the possibility of an outbreak of yellow fever. In accordance with a suggestion from the Chamber of Commerce of Matamoros, Mexico, that, in case a quarantine should be thought necessary, it should be established at Bagdad, instead of at Brownsville, the Governor of Texas has directed the sanitary officers at the latter place to consult with the Mexican authorities.

THE LATE SURGEON-GENERAL BARNES AND THE ARMY MEDICAL MUSEUM.—A general order, issued by the Adjutant-General of the army, announcing the death of Surgeon-General Barnes, which order was published in our issue of April 14th, contained the following statement: "He inaugurated the 'Medical History of the War,' he founded the Medical Museum." Surgeon-General Hammond (retired) having complained that this statement was unjust to himself and to others, the order has been withdrawn, and another has been issued, in which the following words take the place of those quoted above: "Under the fostering care of Edwin M. Stanton, Secretary of War, he accomplished the successful establishment of the Medical History of the War and of the Medical Museum."

SOME POINTS CONNECTED WITH THE LOCAL RECURRENCE OF MALIGNANT DISEASE.—In a recent number of the "Medical Times and Gazette" we find an abstract of a paper on this subject read before the Royal Medical and Chirurgical Society by Mr. Harrison Cripps. He commenced by criticising the view commonly expressed, that local recurrence took place in the cicatrix of the wound, and pointed out that it was rather in the skin and subcutaneous tissue adjacent to the cicatrix that the recurrence was often observed. A paper published by the author in the "Pathological Society's Transactions" of 1881 was referred to, in which microscopic evidence was produced illustrating the view that, as regards malignant disease of the rectum, whether found in the mucous or in the submucous coat of the bowel, it was originally formed of cells derived from Lieberkühn's follicles. A theory founded upon these specimens was also suggested, viz, that the formation of leucocytes was one of the normal functions of the intestinal epithelium. Two cases were narrated in which recurrence of malignant disease undoubtedly first showed itself by cancerous nodules originating in the deeper layer of the cutaneous epithelium by the side of the cicatrix—that is to say, in a part of the skin that had not been removed at the time of operating. After referring to the views of Brodie and other surgeons as to the desirability of removing the entire mammary gland, notwithstanding the cancer may involve only a small portion, Mr. Cripps advised that the same principle should be applied to the superjacent skin. The theory upon which the surgeon advocated the removal of the whole gland-tissue was that, notwithstanding a great portion of it appeared sound, the epithelial lining of the ducts and acini was in reality already affected, and only required time for cancerous growth to become manifest, the epithelium within the gland being in direct continuity with that covering, and the superjacent skin being originally derived from it by involution. Thus the cutaneous epithelial cells lying over the gland were as liable to be implicated as those within it. Mr. Cripps recognized that it was the universal practice of surgeons, when operating for mammary cancer, freely to remove any skin that appeared to be implicated; but he suggested that, even in cases where the skin was soft and supple, longer immunity from recurrence might be possibly obtained by its wide and free removal than by being satisfied with removing a mere elliptical portion involving the nipple.

DEATH OF DR. HOLMES O. PAULDING, UNITED STATES ARMY.—Dr. Holmes O. Paulding, Assistant Surgeon, United States Army, died sud-

denly at Fort Sidney, Nebraska, on Tuesday, the 1st inst. Dr. Paulding was commissioned First Lieutenant and Assistant Surgeon November 10, 1874, and received the rank of Captain November 10, 1879. He was a son of the late Commodore Leonard Paulding, United States Navy.

DR. PIFFARD'S ARTICLES.—Owing to the pressure on our columns, Dr. Piffard's fourth article is unavoidably postponed until a subsequent issue.

ARMY INTELLIGENCE.—*Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from April 23, 1883, to May 5, 1883.*—BAILY, JOSEPH C., Major and Surgeon. To be relieved from duty in the Department of California, and assigned to duty in the Department of Texas. Par. 12, S. O. 102, A. G. O., May 3, 1883. — TILTON, HENRY R., Major and Surgeon. To be relieved from duty in the Department of the Missouri, and assigned to duty in the Department of the East. Par. 13, S. O. 102, A. G. O., May 3, 1883. — BYRNE, CHARLES B., Captain and Assistant Surgeon. To be relieved from duty in the Department of the South, and assigned to duty in the Department of the Missouri. Par. 12, S. O. 102, A. G. O., May 3, 1883. — CRAMPTON, LOUIS W., Captain and Assistant Surgeon. Now awaiting orders, to proceed without delay to Fort Wayne, Michigan, and report to the commanding officer for duty at that post. Par. 2, S. O. 73, Department of the East, April 30, 1883. — PAULDING, HOLMES O., Captain and Assistant Surgeon. To be relieved from duty at Fort Sidney, Nebraska, and assigned to duty at Fort Douglas, Utah. Par. 1, S. O. 42, Department of the Platte, April 25, 1883. — PERLEY, HARRY O., Captain and Assistant Surgeon. To be relieved from duty in the Department of the East, and assigned to duty in the Department of Dakota. Par. 14, S. O. 102, A. G. O., May 3, 1883. — SPENCER, WILLIAM G., Captain and Assistant Surgeon. Now awaiting orders, assigned to duty in the Department of the East. Par. 12, S. O. 102, A. G. O., May 3, 1883. — WORTHINGTON, JAMES C., Captain and Assistant Surgeon. To be relieved from duty in the Department of the East, and assigned to duty in the Department of the Missouri. Par. 14, S. O. 102, A. G. O., May 3, 1883. — BLANT, VICTOR, First Lieutenant and Assistant Surgeon. To be relieved from duty in the Department of the Missouri, and assigned to duty in the Department of Dakota. Par. 13, S. O. 102, A. G. O., May 3, 1883. — MACAULEY, CARTER N. B., First Lieutenant and Assistant Surgeon. To be relieved from duty in the Department of the East, and assigned to duty in the Department of Dakota. Par. 12, S. O. 102, A. G. O., May 3, 1883. — STRONG, NORTON, First Lieutenant and Assistant Surgeon. Upon expiration of leave of absence, to be assigned to duty at Fort Thornburgh, Utah. Par. 2, S. O. 42, Department of the Platte, April 25, 1883.

NAVAL INTELLIGENCE.—*List of Changes in the Medical Corps of the Navy during the week ending May 5, 1883.*—Passed Assistant Surgeon H. L. Law, detached from the Navy Yard, League Island, Pa., on the 10th inst., and ordered to the Yantic. — Passed Assistant Surgeon H. P. Harvey, detached from the Yantic on reporting of relief, and ordered to Chelsea Hospital. — Surgeon William J. Simon, ordered as member of a board at Naval Academy. — Passed Assistant Surgeon W. A. McClurg, detached from the Naval Academy on the 15th inst., and ordered to the United States steamer Dale. — Assistant Surgeon Oliver Diehl, detached from the Naval Academy, and ordered to the Constellation.

SOCIETY MEETINGS FOR THE COMING WEEK.—*Monday, May 14th:* New York Medico-Historical Society (private); New York Ophthalmological Society (private). *Tuesday, May 15th:* Medical Society of the State of Illinois (Peoria); Medical Association of Central New York (Syracuse); Medical Society of the County of Kings; New York Academy of Medicine (Section in Practice); New York Obstetrical Society (private). *Wednesday, May 16th:* Medical Society of the State of West Virginia (Grafton); New Jersey Academy of Medicine (Newark).

ERRATA.—In the editorial "New York as a Medical Center," in our issue of May 5th, p. 492, fourth line, read "services" for "various"; seventh line, read "diversity" for "density"; thirty-sixth line, read "variety" for "rarify."

Lectures and Addresses.

A LECTURE ON

THE TREATMENT OF CHRONIC SUPPURATION OF THE MIDDLE EAR.

DELIVERED IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

By D. B. ST. JOHN ROOSA, M. D., LL. D.,

PROFESSOR OF THE DISEASES OF THE EYE AND EAR; SURGEON TO THE MANHATTAN EYE AND EAR HOSPITAL, ETC.

The name chronic suppuration of the middle ear implies a great deal. It comprehends a large variety of disease in one of the important parts of the body. The ancients gave the name of otorrhœa—a discharge from the ear—to this, and to all other affections in which there was a discharge of pus from the external auditory canal. But this name is defective in the essential quality of a descriptive name or a definition, simply because it is a definition which does not define, and it has been pretty generally discarded by the writers of our time. Now and then attempts are made to revive it, but the love of precision in statement characteristic of our day will render such attempts unavailing. The term chronic suppuration of the middle ear usually implies a perforation of the drumhead or membrana tympani. In exceedingly rare cases there may be a suppuration in the tympanic cavity and mastoid cells, especially in the latter, for weeks or even months, without the occurrence of a perforation of the delicate but firm membrane that forms the boundary between the middle and the external ear. In all but exceptional cases, however, when chronic suppuration of the middle ear is stated to be the diagnosis of a given case, it is meant that the ulceration involves the drumhead. The term perforation, in its turn, includes a great variety of pathological conditions.

For example, the drumhead may be entirely swept away; one half of it may be gone; one third of it may be gone; only a small opening about as large as the head of a pin may exist; two openings may exist; so that in the very appearance of the drumhead we may meet the greatest difference in conditions.

Besides, polypi may be seen through the perforation, springing from the tympanic cavity, or there may be small growths or granulations hardly to be dignified by the term polypi. We may find the opening covered by hardened wax, or even by dried pus. Quite large quantities of mucus, pus, or of mucus, or of a fluid like serum, may conceal the opening and be formed in a quantity sufficient to cause a constant flow into the auditory canal, or the quantity may be very small, and only to be detected on careful examination. In any consideration of the diseases of the middle ear the practitioner should remember that the mastoid cells, as well as the cavity of the tympanum, are an integral portion of this anatomical region. Hence it is that the lining membrane of the mastoid is usually involved in any inflammation of the middle ear. A glance at this cast

of the auditory canal, tympanic cavity, and mastoid cells, made by Dr. Wilson, of the staff of our hospital, will show you how the disease of one part will of necessity extend to the other. In the degree and extent of the inflammation of the mastoid during an *otitis media purulenta* there exists the greatest variability. In regard to caries and necrosis of the tympanic cavity there are also great differences in the morbid changes. The Eustachian tube, a part of the middle ear, as you all know, also furnishes a variety of lesions. Then when we turn to the "little bones of hearing," *ossicula auditus*, we may find a great difference in the changes in different cases. For example, the malleus may be gone wholly or in part, the incus may be gone, or even all three bones may have disappeared. The seventh nerve, in its passage through the canal of Fallopius, may be diseased, and facial paralysis be added to the other ravages of the serious disease which is now being discussed. After these facts are brought to your recollection, you will admit that I am justified in styling the term chronic suppuration of the middle ear a very comprehensive one. It is an erroneous method of teaching which would describe suppuration of the tympanic cavity and mastoid cells by the term otorrhœa, and I think that a discussion of the treatment of a discharge from the ear without a comprehensive view of the important pathological conditions which may exist in this part of the body must be in its very nature misleading. No discussion of the treatment of the formation and discharge of pus from this part of the body will be profitable unless there precedes it a full understanding of the anatomical and pathological conditions which allow this pus to be formed and collected.

If the middle ear were a simple canal or cavity, the principles at the basis of the treatment would, perhaps, be the same that they are now, but it comprises a *series* of anatomical parts, and the details in carrying out these principles are very different, and are much more varied than they would be were we dealing with a simple and easily bounded space. It is the anatomy of the middle ear that makes the treatment of its diseases not an entirely simple matter.

Chronic suppuration of the middle ear is relatively a very common affection. Of a total number of 6,671 cases of aural disease treated in the Manhattan Eye and Ear Hospital in ten years, 1,493, or one in five, were cases of this kind. These statistics are about the same as those of other hospitals. In private practice, however, the proportion of acute cases is larger.

When the suppurative action is fairly established in some or all of the parts of the middle ear, and there is a constant collection of pus or mucus, the first indication in the treatment is the frequent and thorough removal of this baneful secretion. It is a well-settled surgical principle that retained pus is always harmful; that no collections of it are to be allowed if it be possible to remove them. Nowhere is this more true than with reference to the middle ear.

The chief means of treating a chronic suppuration is to be found in a gentle and expeditious removal of the accumulation of pus before its insinuating and corroding properties

have time to do much harm. In a great majority of instances, in my opinion, the syringe and warm water remain the best means of such a cleansing of the ear. Of late objections have been made to the use of the syringe. One authority, for whom I have a great respect, says, in referring to the cleansing of the ear from pus, and in italics, too, "*The syringe, as a rule, is not to be used.*"* When differences of opinion as to modes of treatment arise, there is not much to be said except to show that one recognizes his own standpoint and the difficulties of it, and gives good heed to the contrary one. I think I am not ignorant of the abuse of syringing, or of the fact that much that is called cleansing the ear by syringing has no right to such a name. I am also well aware of the ill effects in isolated cases from syringing. I once reported † a case in which a gentleman who consulted me suffered so seriously from syncope, after a very gentle syringing of the ear, that for some moments it was thought by myself and others that he would certainly die. This patient, however, would probably suffer in the same way from any surgical procedure. After his recovery he told me that he had once fainted in the same alarming way on calling upon a surgeon who proposed to make some kind of an examination. Faintness, vertigo, and nausea are also sometimes produced even by gentle syringing of the ear. Yet, if the proper method is practiced, and the proper care as to gentleness be taken, it is not one case in a hundred in which any unpleasant symptoms will occur. Simple a procedure as it is, the proper method must first be learned. The water should be warmed; it should be injected into the concha before it is allowed to pass into the auditory canal—in short, until you know your patient, you should always proceed very slowly and gently with the syringe, especially in the removal of pus.

But, in spite of all these drawbacks, none of which I would underrate, I believe, as an outcome of twenty years' active experience in aural disease, that it remains the best means, on the whole, in by far the largest number of cases of cleansing the ear. I can not think that the use of warm water to the ear thoroughly and often is any more dangerous, but, on the contrary, of the same amount of good as the use of the same agent in the same way in cleansing fistulous ulcers, open cavities, and other parts of the body which may from time to time become filled with pus. I see no argument in the reasoning that, because warm water may soften the tissue, its use should be avoided for the purpose of cleansing a cavity which requires it. I would advise you, then, in the treatment of chronic suppuration, to consider as a general principle that the ear is to be syringed with warm water in the manner that I now show you, and that you have so often seen practiced here. The best syringe which I have ever seen is one that I lately procured in Paris of Lürer, which has not come into general use, but which we are using in this hospital, and which I am using in my private practice with great satisfaction. It is called the reservoir syringe, and, as you see, it is filled

without any motion of the piston, so that the one action required is the discharge of its contents into the ear. On the withdrawal of the piston it fills itself perfectly, as I now show you. The India-rubber syringes sold in the shops will do very well for patients to use in cases of short duration; in chronic cases a good metallic syringe is required. The fountain syringe is valuable where prolonged irrigation is required, as is also Fayette Taylor's douche. But for ordinary use the piston syringe, made of metal, is the preferable one for the purpose of removing discharges from the ear.

Unless the practitioner has had a large experience in cleansing ears, he should avoid the use of a syringe whose nozzle is long enough and sufficiently slender to enter the auditory canal as far as the junction of the bony with the cartilaginous portion. The slightest unexpected movement of the patient while the syringe is used may cause great harm to the lining membrane of the canal.

After the syringing, the parts should be dried by the use of absorbent cotton twisted about a stick, or the probe cotton-holder, very carefully applied with the aural mirror on the forehead, so that both hands are free. For self-evident reasons, it would never be proper to leave fluid in a cavity upon which medication is about to be applied. After you have secured thorough cleansing of the ears, I believe medication is of secondary importance. Wilde's snare and and Buck's curettes are the best instruments for removing polypi where instrumental interference becomes necessary. Nothing will keep up a discharge of pus from the ear so persistently as a small polypus or granulation. My experience is exactly the same as that of von Trötsch, published in his treatise on the ear, in the first edition of 1862, where he states that he has often seen a discharge of very long standing disappear as in the twinkling of an eye on the removal of a small growth. I think the curettes should be made with sharp edges—not blunt, as first sold in the shops. The profession is very much indebted to Dr. Buck for the suggestion of these very useful instruments for cleaning out the tympanic cavity and auditory canal. I hardly know how I would get on without them after having enjoyed their use for some years. Pedunculated granulations and polypi should be removed as one of the first steps in any continued treatment. Granulations with a broad base are very troublesome, it being very difficult to remove them thoroughly, even when the patient is under observation for a long time. It is often necessary to etherize the patient in order to free the tympanic cavity from granulations. The application of caustics for the removal of polypi or granulations is a large subject. It does not come within the province of this lecture to speak of that except in a very general way. The great prerequisite having been accomplished, of securing a free tympanic cavity, the question then is, What agent shall we choose for the cure of the diseased membrane, and, consequently, for stopping the discharge? A very great deal, of late, has been said about the so-called dry treatment of suppuration of the middle ear. There was a famous peripatetic quack who had a dry treatment which was peculiarly successful for a time. He was in the habit of pouring in plaster-of-Paris for the cure of long-existing discharge of pus from the ear, and the

* "Diseases of the Ear," by A. H. Buck, p. 232.

† "Archives of Otolaryngology," vol. ix, p. 16.

cure for a time was effectual. Much of the so-called dry treatment of to-day will in some cases be as disappointing as was its prototype. The treatment by powders is not particularly new, however. The late Mr. James Hinton was very much in the habit of using French chalk and other powders, and my former assistant, Dr. F. H. Rankin, of Newport, recommended iodoform in diseases of the ear, in an article published in the "New York Medical Journal" some eight or ten years ago, some time after he had successfully used it in this hospital. Treatment by powders is not, therefore, a new subject, although some agents, boric acid in particular, have been used only lately. In spite of all the claims for the exclusive use of powders in the treatment of the ear, and valuable as is their place in our therapeutic resources, I still think that instillations of fluids hold the first rank, and that the use of powders is of secondary value. Whatever may be thought of this view, it is, I think, indisputably sound doctrine that cleansing must precede the use of any agents, and that thorough cleansing is impossible, in many cases, without the use of the syringe.

For the healing of a diseased mucous membrane that has for some weeks or months secreted pus, and which is free from polypi or large granulations, I would advise that fluid applications be first tried. In my practice I use sulphate of zinc, from one to four grains to the ounce; sulphate of alum in the same proportion. Nitrate of silver I use usually upon a cotton-holder, from five to sixty grains to the ounce, or from a long, slender pipette adapted to the middle ear, in the weak solutions. If a strong solution of nitrate of silver be used, it should be at once neutralized with salt and water. I also use alcohol, as suggested by Lowenburg, of Paris, especially in cases where the tissue is granular. A preparation of resorcin, in cases where the mucous discharge exceeds the purulent, is also useful. Boric acid in solution seems to me to accomplish very little. It is, indeed, difficult to say which are the best astringents. But some cases do well with any of the ordinary astringents, and some never cease to be the seat of the formation of pus, no matter how long, how carefully you treat them, and what agents you may use. Carbolic acid and permanganate of potassium have proved worse than useless in my hands.

When solutions do not act well or promptly, powders may be resorted to. Iodoform is valuable in some cases. My associate, Dr. Ely, thinks it especially useful in those cases where the tissues are pallid and have an indolent appearance. Well-triturated boric acid is also a useful agent, although not so efficacious in my hands as it seems to be in those of others.

It is by no means a panacea, no matter how it is applied, or with whatsoever combinations. There are objections to powders which at once suggest themselves when their use is advocated in treating diseased mucous membranes, like those of the nose or middle ear. They are not always absorbed, and they sometimes leave a troublesome, irritating mass behind. Then they occasionally impair the hearing by mechanically obstructing the passage of the sound waves. The solution is poured into the ear, and in from five to ten minutes that which is not absorbed may be allowed to run out. The powder must remain until the ear

is again cleansed, which is not for hours. A tube made from a quill, or one of the powder-blowers especially invented for the purpose, do equally well for forcing the powder into the canal of the tympanic cavity. I do not employ large masses of the powder—simply enough to give the ulcerated or carious portion a good coating.

Solutions are usually much better tolerated by the ear when they are warm. A lighted gas-burner, the flame of a candle, a bowl of hot water, are all convenient means for heating the solution which is to be used.

When powder is employed, the mirror should be used from the forehead, so that you may know just where it has gone, and renew the application if not enough is applied.

Whatever may be said in favor of certain specifics, used either as powders or solutions, certain cases of suppuration of the middle ear will remain uncured in hands never so skillful. They are, from their nature or their environment, incurable. A case of long-standing ulceration in the tympanic cavity and mastoid is almost certain to involve death of the bone more or less superficial. When there is dead bone that can not properly be removed by instruments, solutions of dilute mineral acids, nitric acid and sulphuric—one quarter to one half per cent.—dropped into the ear twice a day (Dr. Urban Pritchard) will be serviceable. An error in treatment, an injudicious mode of life, an undue exposure to wet and cold, may at any time cause the smoldering disease to blaze into a condition that is fatal to life. Pyæmia, meningitis, and cerebral abscess are by no means the infrequent ending of some of those cases. He who has found a panacea for all of them is in a state of mind far removed from a scientific consideration of the conditions which are to be found in chronic suppuration of the middle ear.

When it is said that "a moist treatment of otorrhœa in many instances has a tendency to keep up rather than to check the morbid discharge from the ear,"* if by this language it is meant that careful cleansing of a suppurating middle ear with warm water, and the subsequent instillation of solutions, is in many instances a bad surgical method, I can only answer that this statement, according to my experience, is not borne out by facts. The presence of granulations and polypoid growths does not, in my opinion, contraindicate the use of warm water. Their presence does indicate, however, a necessity for their removal, either by the snare, the forceps, or caustics, *pari passu* with the constant cleansing process. Over and over again, however, have I seen growths shrivel and disappear, under the simple plan of cleansing the ear with warm water, before the operator was ready to remove them by cutting or twisting instruments or by caustics.

I think it very important to inflate the ears very frequently, from two to four times a week, and sometimes daily, by means of Politzer's method, during the treatment of chronic suppuration of the middle ear. The current of air is useful to dislodge inspissated pus or tenacious mucus, and it assists materially in the essential preliminary of all applications; that is, a complete removal of the pus. Sometimes exhaustion of the air from the side of the ex-

* Burnett, "Am. Jour. of the Med. Sci.," January, 1883.

ternal meatus aids in withdrawing mucus from the tympanic cavity. Siegle's instrument, or an ordinary air-bag, may be used for this purpose. Those cases in which there is a constant accumulation of long strings of very tenacious mucus, with very little pus, are exceedingly difficult to manage. The cause for this is to be found in the excessive catarrh of the naso-pharyngeal space, and of the Eustachian tube, which usually accompanies this condition of the tympanic cavity. The mucus is so tenacious in these cases that not even the syringe or the cotton-holder will remove it, but the forceps must be resorted to. Of course, fundamental treatment will begin at the *fons et origo* of the disease of the middle ear, that of the nose and throat. I need hardly say to a class of graduates that the general condition is to be most carefully considered in all cases of chronic local disease. You will often find much to do in this direction in these cases of chronic suppuration of the ear. The restoration of a perforated drumhead is a most interesting reparative process. The ease and rapidity with which they heal in recent cases is startling, and even in chronic cases we are sometimes agreeably surprised to see how soon a *membrana tympani* is restored after simple cleansing of the middle ear has been maintained for a few weeks.

The caustics which I use for removing granulations are fuming nitric acid and chromic acid, as well as solutions of nitrate of silver, from twenty to sixty grains to the ounce. Alcohol is also valuable. Lowenburg, of Paris, first recommended its use in these cases, and I am in the daily habit of using it. I usually cause the granulations to bleed freely by puncturing them with a cataract-needle before applying the caustics.

Burnett* thinks that zinc-drops may supply something which makes the bottom of the auditory canal favorable to the growth of the *aspergillus* or aural fungus. As proof of this is adduced the fact that a fungus is sometimes found in zinc solutions that have been imperfectly stoppered. All the harm that fungi in zinc or other solutions can probably accomplish is to weaken the solution. I consider this objection to zinc or other solutions as unsubstantiated as yet by any facts, and doubtful even from a theoretical point of view, for it is improbable that the fungus would be poured into the ear, but that portion free from it. Besides, the next good syringing with warm water would be an efficient parasiticide if any were necessary, before the growths were established.

In June, 1878, Dr. Edward T. Ely, my associate in private and public practice, made use of skin grafting in the treatment of chronic suppuration of the middle ear. Dr. Ely continued this practice in nine cases occurring among our patients, and I have repeated his experiments. This method of treatment is especially indicated for cases where we can not expect a restoration of the membrane and a cessation of the discharge by the ordinary treatment. The results obtained have not been brilliant, but in two cases a substantial gain in the condition of the tympanic cavity was secured. I have recently performed the operation, but with what result I can not yet say. Dr. Ely's paper

will be found in the "Archives of Otolology," vol. ix, p. 343.

Many cases of chronic suppuration of the middle ear are not cured because the treatment is carried on by the patient himself or by his friends. Very few persons are capable of thoroughly cleansing their own ears. No one is capable of thoroughly cleansing the ear of another unless a special training for this object has been undergone. In fact, a successful treatment of these cases requires the care of a physician. It is easier to learn to clean and dress an ordinary bone fistula than to learn to remove the secretions from an inflamed tympanic cavity and mastoid cells. He who would bring his cases to a successful ending must himself bear the brunt of the labor of treatment. It can not be given over to inexperienced hands. Whenever this personal care of the physician is not to be obtained for these chronic cases, only approximately good results are possible. I have sometimes been able to train a nurse or relative of the patient so that quite thorough cleansing is effected. But this training will require about as much time as is given in one course to a student in the post-graduate school.

The surgeon who is in the frequent habit of examining the *membrana tympani* will find many cases that show how easily an ulcerated drumhead will sometimes heal under very simple or very crude treatment. Cicatricial drumheads are a very common experience in the aural surgeon's observations. A little study of the history of these cases shows that in very many instances they were healed when they were being treated with what we should term neglect. All this should teach us to be very careful students of the healing processes of Nature. In our anxiety to see results from treatment, let us remember to put ourselves in the position of Ambroise Paré, whose benediction to his wounded patient was, "I have dressed you, may God cure you."

All cases of chronic suppuration of the middle ear will not be cured even by good treatment and favorable conditions, while here and there we are surprised to find that some unpromising cases do very well, even under bad circumstances and with no thorough treatment.

To expect too much from treatment, to do too much, is to be meddlesome in intent and action. If we are to make a choice of evils, it is better to be skeptical and inactive than credulous and meddlesome.

It is an interesting fact that very few patients suffering from phthisis pulmonalis ever recover from a suppuration of the ear. Even so far as the accumulation of pus is concerned, no matter how long they may live, the cough usually prevents any healing of the *membrana tympani*. I have one case under observation—the only one I have ever seen—where the discharge and formation of pus have ceased, although the perforation of the membrane does not close.

THE TEXAS STATE MEDICAL SOCIETY, at its recent annual meeting, elected Dr. John A. Wyeth, of New York, an honorary member. Dr. Wyeth was present at the meeting, and made an address on the subject of the progress achieved and to be aimed at in medical education.

A MUNICIPAL LABORATORY OF HYGIENE has been established at Lisbon.

Original Communications.

THE HAIR, ITS USE AND ITS CARE.*

By JOHN V. SHOEMAKER, A. M., M. D.,

PHYSICIAN TO THE PHILADELPHIA HOSPITAL FOR SKIN DISEASES.

THE object of this paper is to briefly describe the hair and its important functions, and to suggest the proper manner of preserving it in a healthy state.

I know full well that much has been written upon this useful part of the human economy, but the constant increase of bald heads and beardless faces, notwithstanding all our modern advancement in the application of remedies to the cure of disease, prompts me to point out to you the many ways of retaining, without medication, the hair, which is a defense, ornamentation, and adornment to the human body.

[Dr. Shoemaker here gave an interesting history of the growth and development of the hair and its uses, which we are compelled to omit. Then, proceeding, he said:] Now, the hair, which fulfills such an important function in the adornment and health of the body, requires both constitutional and local care to keep it in its normal, healthy state. When I say constitutional care I mean that the various organs of the body that assist in nourishing and sustaining the hair-forming apparatus should, by judicious diet, exercise, and attention to the nervous system, be kept healthy and sound, in order that they in turn may assist in preserving the hairs in a vigorous condition.

In the first place, that essential material food, which is necessary to supply the waste and repair of all animal life, should be selected, given, or used according to good judgment and experience.

Thus, mothers should feed their infants at regular intervals according to their age, and not permit them to constantly pull on the breast or the bottle until the little stomach becomes gorged with food, and some alimentary disorder supervenes, often setting up a rash and interfering with the growth and development of the hair. It is likewise important, in case the baby must be artificially fed, to select good nutritious food as near as possible like the mother's—cow's milk, properly prepared, being the only recognized substitute. Care and discretion should likewise be taken by parents and nurses, after the infant has developed into childhood, to give simple, substantial, and varied food at regular periods of the day, and not in such quantities as to overload the stomach. Children need active nutrition to develop them into robust and healthy men and women; and it is from neglect of these important laws of health, and in allowing improper food, that very often bring their results in scald head, ring-worm, and scrofula, that leave their stamp in the poor development of the hair. With the advent of youth and the advance of years, food should be selected and partaken of according to the judgment and experience of its acceptable and wholesome action on the consumer.

The meals should also be taken at regular intervals. At

least four hours should be left between them for the act of digestion and the proper rest of the stomach.

It is, on the contrary, when the voice of nature has been stifled, when judgment and experience have been set aside, that mischief follows; when the stomach is teased and fretted with overloading, and the food gulped down without being masticated, gastric and intestinal derangement supervenes, which is one of the most prolific sources of the early decay and fall of the hair.

The nervous system, which is one of the most important portions of the human structure, and which controls circulation, secretion, and nutrition, often by being impaired, plays a prominent part in the production of baldness. Thus, it has been demonstrated by modern investigation that the nerves of nutrition, by their defective action, are often the cause of thinning and loss of hair. The nutritive action of a part is known to suddenly fail, the hair-forming apparatus ceases to act, the skin changes from a peculiar healthy hue to a white and shining appearance, and often loses at the same time its sensibility; the hairs drop out until very few remain, or the part becomes entirely bald. It is the over-taxing of the physical powers, excessive brain work, the exacting demands made by parents and teachers upon children's mental faculties, the loss of sleep, incessant cares, anxiety, grief, excitement, the sudden depression and exaltation of spirits, irregular and hastily bolted meals, the lack of rest and recreation, the abuse of tobacco, spirits, tea, coffee, and drugs of all forms, that are fruitful sources of this defective action of the nerves of nutrition, and consequent general thinning and loss of hair.

The hair, particularly of the head, should also receive marked local attention. In reference to the use of coverings for it, I know of no better rules than those which I laid down in my chapter on clothing in "Household Practice of Medicine" (vol. i, p. 218, William Wood & Co., New York), in which I state that the head is the only part of the body so protected by nature as to need no artificial covering.

The stiff hats so extensively worn by men produce more or less injury. Premature baldness most frequently first attacks that part of the head where pressure is made by the hat. It is, indeed, a pity that custom has so rigidly decreed that men and women must not appear out of doors with heads uncovered. It would be far better for the hair if to be bare-headed were the rule, and to wear a hat the exception.

Since we can not change our social regulations in this respect, we should endeavor to render them as harmless as possible.

The forms of hats that are least injurious are: for winter, soft hats of light weight, having an open structure, or pierced with numerous holes; for summer, light straws, also of open structure.

As regards the head-covering of women, the fashions have been for several years favorable to proper form. The bonnet and hat have become quite small, and cover but little of the head. This beneficial condition, however, is in part counterbalanced by the weight of false curls, switches, puffs, etc., by the aid of which women dress the head.

* Abstract of a paper read before the Pennsylvania State Medical Society, at Norristown, May 10, 1888.

These, by interfering with evaporation of the secretions, prevent proper regulations of the temperature of the scalp, and likewise lead to the retention of a certain amount of excrementitious matter, both of which are prolific sources of rapid thinning and loss of hair in women.

False hair has likewise sometimes been the means of introducing parasites, which give rise to obstinate affections of the scalp.

Cleanliness of the entire surface of the skin should next demand attention, and that should be done by using water as the medium of ablution. It is a well-known physiological law that it is necessary, in order to enable the skin to carry on its healthful action, to have washed off with water the constant cast of scales which become mingled with the unctuous and saline products, together with particles of dirt which coat over the pores, and thus interfere with the development of the hairs. Water for ablution can be of any temperature that may be acceptable and agreeable, according to the custom and condition of the bather's health. Many chemical substances can be combined with water to cleanse these effete productions from the skin. Soap is the most efficacious of all for cleanliness, health, and the avoidance of disease. Soap combines better with water to render these unctuous products miscible, and readily removes them thoroughly from the skin. The best variety of soap to use is the pure white soap, which can not be so easily adulterated by coloring material, or disguised by some perfume or medicinal substance. Ablution with soap and water should be performed once or twice a week at least, particularly to the head and beard, in order to keep open the hair tubes so that they may take in oxygen, give out carbon, carry on their nutrition, and maintain the hairs in a fine, polished, and healthy condition. In using water to the scalp and beard, care should be taken not to use soap-water too frequently, as it often causes irritation of the glands, and leads to the formation of scurf. It is equally important to avoid using on the head the daily shower-bath, which, by its sudden, rapid, and heavy fall, excites local irritation, and, as a result, loss of hair quickly follows. In case the health demands the shower-bath, the hair should be protected by a bathing cap. The most acceptable time to wash the hair, to those not accustomed to doing it with their morning bath, is just before retiring, in order to avoid going into the open air or getting into a draught and taking cold. After washing, the hair should be briskly rubbed with rough towels, the Turkish towel heated being particularly serviceable. Those who are delicate or sick, and fear taking cold or being chilled from the wet or damp hairs, should rub into the scalp a little bay rum, alcohol, or oil, a short time after the parts have been well chafed with towels. The oil is particularly serviceable at this period, as it is better absorbed, and at the same time overcomes any dryness of the skin which often follows washing.

It might be well to add in this connection that I have frequently been consulted, by those taking salt-water baths, as to the care of the hair during and after the bath. If the bather is in good health, and the hair is normal, the bather can go into the surf and remain at least fifteen

minutes, and on coming out should rub the hair thoroughly dry with towels.

Ladies should permit it to remain loose while doing so, after which it can be advantageously dressed.

It is, however, often injurious to both men and women having some wasting of the hair to go into the surf without properly protecting the head; the sea water has not, as is often thought, a tonic action on the scalp; on the contrary, it often excites irritation and general thinning. Again, it is most decidedly injurious to the hair for persons to remain in the surf one or two hours, the hair wet, and the head unprotected from the rays of the sun. This latter class of bathers, and those who hurriedly dress the hair wet, which soon becomes moldy and emits a disagreeable odor, are frequent sufferers from general loss and thinning of the hair.

An agreeable and efficient adjunct after ablution, which I have already referred to, is oil. Oil has not only a cleansing action upon the scalp, but it also overcomes any rough or uneven state of the hair, and gives it a soft and glossy appearance.

The oil of ergot is particularly serviceable in fulfilling these indications, and, at the same time, by its soothing and slight astringent action upon the glands, will arrest the formation of scurf. In using oil, the animal and vegetable oils should always be preferred, as mineral oils, especially the petroleum products, have a very poor affinity for animal tissues.

Pomatum is largely used by many in place of oil, as it remains on the surface and gives a full appearance to the hairs, thus hiding, sometimes, the thinness of the hair.

It will do no harm or no special good if it contains pure grease, wax, harmless perfume, and coloring matter, but it is often highly adulterated, or, the fat in it decomposing, sets up irritation on the part to which it is applied. I therefore always advise against its use.

The comb and brush are also agents of the toilet by which the hair is kept clean, vigorous, and healthy. The comb should be of flexible gum, with large, broad, blunt, round, and coarse teeth, having plenty of elasticity. It should be used to remove from the hairs any scurf or dirt that may have become entangled in them, to separate the hairs and prevent them from becoming matted and twisted together.

The fine-tooth comb, made with the teeth much closer together, can be used in place of the regular toilet comb just named when the hair is filled with very fine particles of scurf, dirt, or when parasites and their eggs infest the hairs. It should, however, always be borne in mind that combs are only for the hair, and not for the scalp or the skin, which is too often torn and dug up by carelessly and roughly pulling these valuable and important articles of toilet through the skin as well as the hair.

The brush with moderately stiff whalebone bristles may be passed gently over the hair several times during the day, to brush out the dust and the dandruff, and to keep the hair smooth, soft, and clean; rough and hard brushing the hair with brushes having very stiff bristles in them, especially the metal or wire bristles, is of no service, but often irritates the parts and causes the hair to fall out. [Dr. Shoe-

maker then denounced the use of the so-called electric brush, saying its use was injurious, as also was the effort to remove dandruff by the aid of the comb and brush. Continuing, he remarked:] And now the question arises, Should the hair be periodically cut? It may be that cutting and shaving may for the time increase the action of the growth, but it has no permanent effect either upon the hair-bulb or the hair-sac, and will not in any way add to the life of the hair.

On the contrary, cutting and shaving will cause the hair to grow longer for the time being, but in the end will inevitably shorten its term of life by exhausting the nutritive action of the hair-forming apparatus. When the hairs are frequently cut, they will usually become coarser, often losing the beautiful gloss of the fine and delicate hairs. The pigment will likewise change—brown, for instance, becoming chestnut, and black changing to a dark brown. In addition, the ends of very many will be split and ragged, presenting a brush-like appearance. If the hairs appear stunted in their growth upon portions of the scalp or beard, or gray hairs crop up here and there, the method of clipping off the ends of the short hairs, of plucking out the ragged, withered, and gray hairs, will allow them to grow stronger, longer, and thicker.

Mothers, in rearing their children, should not cut their hair at certain periods of the year (during the superstitious time of full moon), in order to increase its length and luxuriance as they bloom into womanhood and manhood. This habit of cutting the hair of children brings evil in place of good, and is also condemned by the distinguished worker in this department, Professor Kaposi, of Vienna, who states that it is well known that the hair of women who possess luxuriant locks from the time of girlhood never again attains its original length after having once been cut.

Pincus has made the same observation by frequent experiment, and he adds that there is a general opinion that frequent cutting of the hair increases its length; but the effect is different from that generally supposed. Thus, upon one occasion he states that he cut off circles of hair an inch in diameter on the heads of healthy men, and from week to week compared the intensity of growth of the shorn place with the rest of the hair. The result was surprising to this close and careful observer, as he found in some cases the numbers were equal, but generally the growth became slower after cutting, and he has never observed an increase in rapidity.

I might also add that I believe many beardless faces and bald heads in middle and advancing age are often due to constant cutting and shaving in early life. The young girls and boys seen daily upon our streets with their closely cropped heads, and the young men with their clean-shaven faces, are, year by year, by this fashion, having their hair-forming apparatus overstrained.

I also must condemn the modern practice of curling and crimping, the use of bandoline, powders, and all varieties of gum solutions, sharp hair-pins, long-pointed metal ornaments and hair combs, the wearing of chignons, false plaits, curls, and frizzes, as the latter are liable to cause headaches and tend to congestion. Likewise I protest against the use of castor-oil and the various mixtures extolled as the best

hair-tonics, restoratives, vegetable hair-dyes, or depilatories, as they are highly injurious instead of beneficial, the majority of hair-dyes being largely composed of lead salts. But, should your patients wish to hide their gray hairs, probably the best hair-dye that can be used safely is pyrogallic acid or walnut-juice, the hairs being first washed with an alkaline solution to get rid of the grease. Nitrate of silver is also a good and safe hair-dye, but its application should be done by one experienced in its use. The judicious use of these hair-dyes will give the hair above the surface of the skin a brownish-black appearance, the intensity of the color of which depends upon the strength of the solution. But hair-dyeing for premature grayness should be avoided, as the diseased condition may be averted by the proper remedies. Never permit the hair to be bleached for the purpose of obtaining the fashionable golden hue, as the arsenical solution generally used is highly dangerous; but, if your patients must have their hair of a golden color, insist upon their hair-dresser using the peroxide of hydrogen, which is less dangerous than the preparation first mentioned.

Perhaps one of the most pernicious compounds used for the hair at the present day is that which is sold in the shops as a depilatory. It is usually a mixture of quicklime and arsenic, and is wrongly used and recommended at this time by many physicians to remove hairy moles and an excessive growth of hair upon ladies' faces. Its application excites inflammation of the skin; and, while it removes the hair from the surface for the time, it often leaves a scar, or makes the part rough, congested, and deformed.

In the mean time, the hair will grow after a short period stronger, coarser, and changed in color, which will even more disfigure the person's countenance. With the present scientific knowledge of the application of electrolysis, hairs can be removed from the face of ladies or children, or in any improper situation, in the most harmless manner without using such obnoxious and injurious compounds as depilatories.

In conclusion, let me add that, if the hair becomes altered in texture, or falls out gradually or suddenly, or changes in color, a disease of the hair, either locally or generally, has set in, and the hair, and perhaps the constitution, now needs, as in any other disease, the constant care of the physician.

A general remedy for this or that hair disease that may develop will not answer, as hair diseases, like other affections, have no one remedy which will overcome wasting, thinning, or loss of color. Patients, reasoning upon this belief, frequently apply to me for a remedy to restore their hair to its full vigor or give them back its color. I always reply that I have no such remedy.

The general health, as well as the scalp and hairs, must be examined carefully, particularly the latter, with the lens and microscope. All changes must be watched, and the treatment varied from time to time according to the indications.

No one remedy can, therefore, under any circumstances, suit, as the remedy used to-day may be changed at the next or succeeding visit. No remedy for the hair will be neces-

sary if the foregoing advice be followed which I have just narrated, and which is the result of some seven years of labor and experience.

The proper consideration and putting into practice of these suggestions will most certainly secure to the rising generation fewer bald heads and more luxuriant hair than is possessed at the present day.

THE PATHOLOGY AND RADICAL CURE OF HAY FEVER, OR HAY ASTHMA.

By JOHN O. ROE, M. D.,

ROCHESTER, N. Y.,

FELLOW OF THE AMERICAN LARYNGOLOGICAL ASSOCIATION, MEMBER OF THE MEDICAL SOCIETY OF THE STATE OF NEW YORK, OF THE AMERICAN MEDICAL ASSOCIATION, ETC.

(Concluded from page 512.)

The importance of unobstructed nasal passages and free nasal respiration is generally recognized, but, in seeking for the cause of the symptoms which arise when these passages are obstructed, the nose is quite commonly overlooked. It is for this reason that I have purposely discussed somewhat in detail this sympathetic connection which exists to a greater or less degree between the nasal cavity and other parts and organs, and have endeavored to make it clear that the train of symptoms attending this affection, as suffusion and irritation of the eyes, sneezing, asthma, and other local or systemic derangements, is the result of this intense local irritation set up in the tissue of the nasal passages by these irritating substances.

In this relationship I also wish to point out that latent, as well as active, disease of this tissue will in many instances excite in it a hyperæsthesia or an inordinate sensitiveness to local impression.

The conclusion that this hyperæsthetic tissue of the nasal passages sustains a certain relation to the causation of hay fever has been reached in a natural manner by observing from time to time that patients who were under treatment for nasal diseases, and who also suffered severely from hay fever during the summer months, were relieved, or their attacks lessened in severity, in proportion as these diseased conditions in the nasal passages were removed; and that, in cases where this hypertrophied turbinated tissue was removed altogether, the patient became entirely exempt from subsequent attacks.

It has been observed, furthermore, that in every instance in those who were subject to hay fever, more or less disease or hypertrophy of this tissue existed, although hyperæsthesia of this tissue is induced in but a portion of those in whom this hypertrophy is found; and, as this hypertrophy is the cause, in nearly all cases, of what is termed nasal catarrh, so we find that hay fever is most prevalent in those regions where there is a predisposition to catarrhal diseases, and where the atmospheric conditions are such as to cause these hypertrophies.

By way of illustration, I will cite some well-marked and typical cases of hay fever which were entirely relieved by treatment of the nasal disease.

F. J. T., farmer, aged thirty-three years, was referred to

me by my late friend Dr. J. I. Denman, November 18, 1878. For twelve years previous he had more or less sensitiveness in the nose and throat, and was subject to frequent colds in the head. Early in the fall of 1876, while at the Centennial, he took a heavy cold in the head, which did not leave him as his colds had done before.

Shortly after this he had a watery, and later a thick and tenacious, discharge from the nose, which continued until I saw him.

In the fall of 1879 his nostrils became narrowed so that he had much difficulty in breathing through them, particularly at night on lying down. His sleep was disturbed by loud snoring, he was frequently aroused by attacks of dyspnoea, and in the morning his throat would be dry, with a bad taste in his mouth. He also remarked in this connection that he had been a sufferer from hay fever during these twelve years, and that it was becoming more severe each year.

His attacks came on about the 1st of July, during hay-fever time, and continued until early fall, and were attended with severe asthmatic attacks. They were becoming so severe that often he had to refrain from working in the field, and to shut himself up in the house; and frequently during the winter, on shaking dry hay to feed his horses, symptoms similar to his summer attacks would be brought on. Other forms of dust and also damp air affected him. He especially wished to know if these attacks of hay fever could be prevented. I told him the only sure way was to take an ocean voyage, or to go to some locality where hay fever sufferers were exempt.

An examination showed both nostrils to be greatly narrowed by inferior turbinated hypertrophy; also that there was pharyngo-laryngeal catarrh, a markedly scroled and somewhat omega-shaped epiglottis with two small cysts near the tip on the lingual side.

In addition to the removal of the cysts, and topical treatment to the larynx and pharynx, I advised the removal of the turbinated hypertrophy with the galvano-cautery, to which he most cheerfully consented.

On the thorough removal of this hypertrophied tissue from the nose, and the cure of the disease in the throat, he was entirely relieved of the irritation in the nose, the discharge ceased, and he was troubled no more by snoring and attacks of dyspnoea at night.

Greatly to his, and also to my own surprise, he was not attacked by hay fever during the following summer; and, as he informed me a short time ago, he has been entirely exempt from it during each summer since.

G. B., aged thirty-three, merchant, was referred to me April 5, 1880, for treatment for marked nasal obstruction and nasal catarrh of ten years' standing. He stated that during each season he had had hay fever and hay asthma very severely, coming on about the 25th of July and continuing the remainder of the summer, oftentimes so severely as to compel him to seek relief at some reputed resort.

He was subject to frequent colds in the head, and had difficulty in breathing through the nose, with irritation in the throat and impairment and muffling of his voice, though he was not markedly hoarse.

An examination revealed in both nostrils marked anterior turbinate hypertrophy, the right nostril being nearly occluded.

Treatment.—I advised removal of this tissue with the galvano-cautery, which was done April 12th, which resulted in restoring free nasal respiration, removing his annoying catarrh, and, greatly to his surprise, giving him entire immunity from hay fever during the two summers which followed.

Mr. C. S., Abilene, Kansas, aged thirty-four years, a stout, well developed man, came under my care December 31, 1881. He had been troubled more or less with naso-pharyngeal catarrh since he had scarlet fever, twenty years ago; and, during each summer, with hay fever, coming on about the 15th of August and continuing until frost came, and attended by more or less asthma. He was not free at any time from a sensitiveness about the throat and nostrils, and some difficulty in breathing through them when exposed to damp air or dust. He was also subject to frequent colds and attacks of hoarseness, with cough, and sometimes difficulty in articulation. His general health was good. An examination revealed marked hypertrophy of the vascular tissue covering the inferior turbinated bones and the lower portion of the septum, and also pharyngo-laryngeal catarrh.

Treatment.—I advised removal of the tissue obstruction in the nostrils and local medication to the larynx and pharynx. Wishing to avoid, if possible, all operative procedures, he decided to try the effect of local medication alone. Accordingly, for four weeks the most efficient and approved local medicaments were employed, with marked benefit, to the laryngeal affection, but with only temporary relief to the nasal obstruction. He went home, but returned April 8th, ten weeks afterward, to have the hypertrophied turbinated tissue removed, which was thoroughly done in both nostrils, the posterior turbinated hypertrophy with Jarvis's snare, the middle and anterior hypertrophy with the galvano-cautery. Local applications were also continued to the larynx, pharynx, and the surrounding slightly diseased portions of the nasal passages. He returned home May 15th, with complete relief from all his old nasal and laryngeal affections. In a letter received from him but a short time ago he states that he escaped the hay fever last summer, and has since remained very well.

Mrs. J. W. K., aged thirty-one years, was referred to me February 2, 1882. She had had nasal catarrh and obstructed nostrils for eight years, and each summer during this time hay fever very severely. Four years ago she began to have frequent and severe headaches, profuse discharge from the nose, loss of smell in the left side, and tinnitus aurium. She had also become unable to use her eyes to read or sew, on account of intense headache which was immediately brought on. Her general health was much below par, and she was weak and anemic.

Examination.—Obstructed nostrils from turbinated hypertrophy and chronic follicular pharyngitis.

Treatment.—I advised the removal of this turbinated tissue, which was done February 12th, in both nostrils, with the galvano-cautery. The operation, with some attendant treatment, resulted in complete relief of the nasal stenosis, disappearance of the headaches on using the eyes or at any other

time, and marked improvement in her general health. She also escaped completely, last summer, her annual attack of hay fever.

Miss L. C., aged twenty-two years, vocalist, consulted me May 20, 1882, in regard to an impediment in her singing voice and pharyngeal irritation; and also in regard to hay fever and asthma, which had attacked her every year in July for eight years. This she wished prevented if possible, as she was unable to sing during the remainder of the summer. At other times she felt very well, and had no special trouble from catarrh or nasal obstruction unless exposed to the inhalation of dust.

Examination showed the vocal disability to be due mainly to hypertrophied tonsils. In the nose there was considerable hypertrophy of the turbinated tissue, which slightly impaired the nasal resonance, but which, owing to the large size of the passages, did not obstruct nasal respiration. Removal of the tonsils greatly improved the voice. She decided to have the nasal hypertrophy removed, to avoid, if possible, the hay fever. This was done June 21st, the posterior portion with Jarvis's nasal wire écarteur, the middle and anterior by the galvano-cautery. After the healing of the parts, the sensitiveness to exposure to dust was removed, and she has this summer completely escaped her annual attacks of hay fever.

In all these cases it will be seen that the galvanic cautery was used either alone or as a supplement to the use of the snare.

In many cases, on attempting to remove the nasal hypertrophies with the snare alone, or by the employment of caustics, as nitric acid, chromic acid, acetic acid, etc., the attacks of hay fever were to a greater or less degree lessened, but not altogether prevented; although at that time it was supposed to be only an accidental complication, the connection between it and the hypertrophy of the turbinated tissue not then having been recognized.

For the removal of this tissue, Jarvis's snare is the most efficient means of removing that at the posterior end of the turbinated bone, as the tissue here is usually more or less pedunculated and can be readily engaged in the loop; while that covering the middle and anterior portion of the turbinated bone is almost always sessile, and it is rare that enough of this tissue, and particularly the deep plexuses of vessels, can be removed by it to be effective, even when the clamp-forceps or the transfixion needle is used.

In the employment of caustics, the mucous and cellular tissue is readily removed, but the vessels, being much more resisting, are not destroyed.

The galvanic cautery, therefore, is the most reliable and radical method to employ.

It serves a threefold purpose: that of destroying the tissues and vessels with which the electrode comes in contact, of obliterating the surrounding vessels by the plastic exudate which is thrown out, and of removing the hyperæsthesia of the terminal nerve-fibers in the part.

By using a small electrode and burning but little at each introduction, to avoid the excessive heating of the surrounding tissues, and afterward, by keeping the parts protected by vaseline warmed and thrown into the nostrils with the spray tube immediately after the operation and

until the slough separates and the parts are healed, and avoiding during this time the use of aqueous solutions, the inflammatory complications which have so frequently occurred can be almost invariably prevented. On burning but little at each introduction of the electrode it is usually necessary to introduce it several times before the destruction of the tissue is accomplished; but this is far preferable to burning it all off at one introduction of the electrode, and pain is thereby almost completely avoided.

This opinion that nasal disease is the direct cause which predisposes to attacks of hay fever is also supported by Dr. Daly, of Pittsburgh, in a recent article on the "Relations of Hay Asthma and Chronic Naso-Pharyngeal Catarrh." ("Archives of Laryngology," April, 1882, vol. iii, p. 157.)

In this article Dr. Daly reports the histories of three patients who were chronic sufferers from hay fever, for six, fifteen, and twenty-one years, and, in every instance where he removed this turbinated hypertrophy and cured the nasal disease, the patients were given complete immunity from further attacks, although constantly exposed to the same influences which had affected them so severely before.

Thus, from the study of hay fever in the light of the most recent investigations as to its cause, and our present knowledge of nasal diseases and their influence on other organs, we may draw the following conclusions:

1. That hay fever is an affection not confined to age, sex, or condition in life.

2. That it is excited by the pollen of flowers or grasses, dust, or other irritating substances floating in the atmosphere, which are brought, by inhalation, in contact with the nasal and bronchial mucous membrane.

3. That the nasal mucous membrane in certain individuals is very susceptible to the irritating effect of these substances, while in others it is not.

4. That this hyperæsthesia is associated with or occasioned by a diseased condition, either latent or active, of the naso-pharyngeal mucous membrane and with an hypertrophied condition of the vascular tissue covering the turbinated bones and the lower portion of the septum.

5. That the systemic disturbances, such as asthma, etc., are the effect of the local irritation of this diseased tissue in the nasal passages which is reflected to the larynx, bronchi, and lungs, causing in them a fluctuatory hyperæmia, produced through the correlating function of the sympathetic ganglia connecting these different regions.

6. That the treatment during the attack can only be palliative, such as to soothe the inflamed parts and to quiet the systemic disturbance which may be occasioned.

7. That in most cases the only effective relief, during the attack, consists in going to a seaport or mountainous region, or to any locality where the air is free from the substance which produces the irritation.

8. That curative measures can only be adopted when the individual is free from the attack.

9. That the removal of the diseased tissue in the nasal passages removes the susceptibility of the individual to future attacks of hay fever.

Clinical Reports.

ST. LUKE'S HOSPITAL.

Reported by CHARLES A. KINCH, M. D.*

(SERVICE OF DR. BEVERLEY ROBINSON.)

THREE CASES OF TYPHOID FEVER; BILIARY CALCULUS AND JAUNDICE; ERYTHEMA NODOSUM.

DURING the last autumn a number of cases of typhoid fever have been treated in the hospital. Of them three are selected as presenting courses of temperature of peculiar interest.

CASE I.—UNCOMPLICATED TYPHOID FEVER OF LONG DURATION.

James, aged twenty-four; single; Ireland; coachman; admitted August 31st.

Ten days before this young man came to the hospital he began to have headache, vomiting, and chilly sensations, with indispotion to work. He had no epistaxis, and was very much constipated. He was compelled to go to bed five days ago.

He was bright, and perfectly intelligent on admission, but had high temperature (104° F.), pain in both iliac fossæ, and marked gurgling. There were no spots on the abdomen. He was put upon milk diet and dilute nitric acid drink.

September 2d.—The patient was seized with vomiting. The ejected matters consisted of milk and some blood and mucus.

3d-8th.—The milk was given in small quantities. An enema was given every second day to unload the bowels.

9th.—During the evening the fever reached 104.8°. A bath caused a rapid reduction of 4.6°. The patient had a chill. Brandy and chloroform were freely administered, and in two hours the temperature rose again to 104°. The pulse was good. Examination of the chest the next morning showed slight dullness at the base of both lungs, but no changes in the voice, sounds, or breathing. After this sponge baths were given instead of immersions.

13th.—No special change. The general condition was apparently not much affected by the high temperature.

27th.—Though the patient had been taking quinine and brandy, the temperature continues high. The pulse was good. The bowels had been opened only by enemata.

October 5th.—The temperature presented wide oscillations. The tongue was moister. The mental condition was good.

9th.—The patient was improving. He began to ask for something to eat.

27th.—He had normal temperature.

November 2d.—To-day the first solid food was taken. The patient had profuse sweatings, and his temperature was subnormal.

23d.—The man had gained nine pounds in the past week. He had received light diet, and quin. sulph., gr. v (0.33), *bis die*.

December 15th.—Discharged cured.

CASE II.—TYPHOID FEVER COMPLICATED WITH ACUTE PLEURISY.

William, aged thirty-two; widower; Ireland; employed in the gas-works; admitted October 31st.

Two weeks ago this patient began to suffer pain in the head and limbs, and lost appetite. A week later he began to be feverish, and had pain of moderate severity in the right iliac fossa. He had no diarrhoea. Four days ago he felt weak enough to go to bed, and he bled from the nose yesterday.

On admission, the patient, a well-nourished man, exhibited

* From notes kindly furnished by Dr. Moffatt, house physician, and Dr. Devlin, senior assistant.

1° James

2° William

3° Annie

a few suspicious spots on the abdomen, a tongue slightly coated, and a dicrotic, feeble pulse. His mind was sluggish, though perfectly rational. He was given milk diet, whisky, and black coffee.

November 3d.—Numerous typhoid papules existed on the skin. The heart's action was exceedingly rapid, and its sounds indistinct and feeble. In the second interspace there was prolongation of the first sound. There were a few subcrepitant râles at the level of the second rib on the left side. The patient was delirious. The quantity of stimulant was increased, and a mixture containing two grains (0.13) of carbonate of ammonium and two minims (0.13) each of the tinctures of digitalis, nux vomica, and belladonna, was to be given every two hours. Opium was administered cautiously in grain doses.

4th.—The patient was perfectly rational. His pulse was easily counted, 120 to the minute, but weak.

8th.—The temperature was moderately elevated. The tongue was slightly coated and moist. The bowels were opened thrice daily with yellow liquid stools.

10th.—An acute pleuritis had developed in the left side. A solution of morphine was injected under the skin over the affected part, and a sinapism applied.

12th.—The bowels required to be moved by an enema.

16th.—There was again some pain in the side. The cautery was used, and twenty-five grains (1.66) of quinine given to control the fever.

23d.— \mathcal{R} Ol. terebinth, mij (0.13), every two hours.

December 5th.—He was passing seventy ounces (2.17 litres) of urine daily, and sweating profusely. The first sound of the heart was prolonged. The temperature was slightly elevated. Stop Ol. terebinth. \mathcal{R} Caffein. citrat., gr. ij (0.13), every two hours.

9th.—Less sweating. Stop caffeine. It had not acted satisfactorily as a stimulant. \mathcal{R} Pil. ferri carbonat., gr. ij (0.40), three times a day.

10th.— \mathcal{R} Ext. convallariæ fl., $\text{m}\nu$ (0.33), every three hours.

12th.—The heart sounds were weak but regular. Pulse, 96.

25th.—Candy was distributed through the ward, and this patient had been eating some of it. His temperature was elevated.

January 5th.—Temperature normal.

22d.—The patient had been improving steadily.

23d.—He desired to go home. Discharged cured.

CASE III.—TYPHOID FEVER WITH RELAPSE.

Annie, aged twenty-two; single; Ireland; domestic; admitted September 22d.

This young woman, six weeks before admission, had a slight chill, followed by fever and sweating. This had been repeated every day up to date. She had had headache and pain through the small of the back. She had vomited a good deal. She had had severe diarrhoea up to within a few days ago, and some abdominal pain. There was no tenderness on pressure, but gurgling in the right iliac fossa. She complained of pain over the region of the spleen. Some spots were visible on the skin of the abdomen. She had had no epistaxis, and had been confined to the bed only one day.

Milk diet and dilute nitric acid drink were ordered.

September 23d.—The temperature rose high, and a bath was given. Half an ounce (16.00) of brandy was given before the bath, and also repeated every six hours.

October 1st.—The temperature was falling. The bowels required an enema to move them.

7th.—Improvement continued. The patient was permitted to eat toast without crust.

13th.—The temperature had been rising. Milk diet was resumed.

15th–16th.— \mathcal{R} Quin. sulph., gr. xx (1.33), at seven, and gr. x (0.66) at eight in the morning.

19th.—The bowels were constipated.

23d.—There was a plentiful eruption of typhoid spots.

26th.—The patient was decidedly better. Her face was brighter, and she had appetite. The eruption was fading.

November 16th.—The temperature was rising.

24th.—A few rose-spots again appeared on the abdomen.

December 1st.—The first sound of the heart seemed sometimes to be doubled. \mathcal{R} Caffein., gr. ij (0.13), every three hours.

3d.—There was a decided reduction in the temperature.

4th.—She slept well. Stopped caffeine.

18th.—The temperature was now normal.

January 15th.—The patient received "light diet." She was informed to-day by one of her family that her sister had died in this hospital during the summer, and also that her father had lately died. Her sister had been exposed to the same source of infection in an out-of-town hotel, and, being brought to the hospital, had died in the third week. This sad news depressed her mind very much, and she desired to leave. Discharged cured.

BILIARY CALCULUS AND JAUNDICE.

Jane, aged thirty-eight; married; United States; domestic. Admitted December 5th.

This patient had, five years ago, an attack consisting of very severe pain in the epigastrium and right hypochondrium, with vomiting, jaundice, fever, and constipation. The acute symptoms subsided after about two weeks. Two years ago, and again last spring, she had similar attacks, but not so severe. Since the last she has been quite well until two weeks ago, when she began to suffer nausea, vomiting, and general malaise. She was treated by a non-professional "sister," and salivated with calomel.

One week ago, after exposure during her menses, she had a slight chill, followed by febrile movement and severe uterine tenesmus. A couple of days later she passed a clot the size of a chestnut. Her menses had previously been quite regular.

She now complained of pain in the epigastrium. Her uterus was tender on pressure, and she had leucorrhœa. Her bowels were constipated, and appetite poor. She had had no vomiting or jaundice during the last few days.

It was thought that her attacks of pain, of which she had given the history, were caused by the passage of gall-stones. Her endometritis was treated with benefit until

December 22d. when she vomited several times, and the next day developed an icteroid hue. \mathcal{R} Bismuth, gr. x (0.66), morph. sulph., gr. $\frac{1}{2}$ (0.005), every four hours, together with pil. podophylli co. no. j at bed hour.

28th.—There were pain and tenderness over the gall-bladder, but no distension was apparent.

30th.—Stop bismuth and morphine powders. \mathcal{R} Sod. sulph., 3j (4.00), every three hours.

31st.—There was a fresh accession of jaundice and renewed vomiting. She had no pain. For the sulphate of sodium substituted Carlsbad water, 3j (60.00), three times a day.

January 4th.—The jaundice was deepening.

8th.—No improvement. Stopped Carlsbad and gave euonymin, gr. j (0.066), and a "pearl of ether" alternately three hours apart.

12th.—The patient was allowed to take one bottle of natural Vichy (Grande Grille) daily. She must avoid cheese, butter, fat, tea, sugar, and potatoes. She might eat moderately of green vegetables.

15th.—R Sod. bicarb., gr. xx (1.33), sp. camphor, ʒ ss. (2.00), aq. Vichy, ʒ ij (60.00). M. S. Every three hours.

23d.—The jaundice was fading quite markedly. The bowels were again constipated. R Sod. sulphat., ʒ ij (60.00), every morning.

February 2d.—R Pil. ferri carbonat., gr. v (0.33), three times a day.

20th.—The patient was nearly well.

ERYTHEMA NODOSUM.

Louisa, aged eighteen; single; United States; nurse. Admitted December 6th.

This patient never had rheumatism. She had suffered from various dyspeptic symptoms for a year or more—sour eructations, flatulence, and constipation. She had no menstrual derangement. One week ago there appeared suddenly on her legs numerous elevated painful spots, hard to the touch, tense and red. In a few days they also appeared on the thighs and arms. At that time the patient had an attack of severe headache, dizziness, and vertigo, with a considerable rise of temperature.

On admission, the patient, well nourished, complained of nothing but tenderness of the spots above mentioned. These spots were dark-blue or greenish in color, and looked like bruises. Her appetite was poor, and bowels constipated. Pulse, 102; temperature, 102.4°. The urine contained abundant urates.

R Sod. bicarb., gr. xx (1.33), in Vichy water, once in three hours.

December 7th.—The bowels were freely moved by saline mixture.

9th.—The patient complained of pain in the left side. Physical examination revealed a little pleuritic roughening around the base of the lung, and a small amount of effusion posteriorly. A blister was ordered.

12th.—The saline laxative was again required. R Ae. nitro-hydrochloric, dilut., ʒ xv (1.00), infus. quassia, ʒ ss. (16.00). M. S. Three times a day.

14th.—The temperature remained elevated. The spots had disappeared, and the patient complained of no pain. R Quin. s., gr. v (0.33), twice a day.

19th.—No trace of the eruption remained.

22d.—She complained of pain in the left side. There was no pleuritic crackling. Temperature, 102°.

23d.—Temperature normal. She complained of slight sore throat.

28th.—Yesterday the erythema nodosum returned on the legs and arms and right forearm. For the intercostal neuralgia gave tr. bryoniae, ʒ x (0.66), every four hours.

29th.—Liniment. aconit., locally. Stopped ac. nitric. and infus. quassia. R Sod. bicarb., gr. xx (1.33), three times a day.

January 3d.—Erythema subsiding. Discharged improved.

Book Notices.

On Slight Ailments: their Nature and Treatment. By LIOUEN S. BEALE, M. B., F. R. S., F. R. C. P., Professor of the Principles and Practice of Medicine in King's College, London, etc. Second edition, enlarged and illustrated. Philadelphia: P. Blakiston, Son & Co., 1882. Pp. 283.

AN extended review of this attractive little volume would be unnecessary, since it has already met with such a favorable reception in a former edition. It is not, as might be inferred from the title, one of those mediocre hand-books, such as are

becoming a drug in the medical market, but the recorded experience of a scientific physician.

The pervading tone of the work, as outlined in the introduction, is elevated: its key-note is truth and honor versus quackery. Perhaps, however, there is a shade of bitterness in the author's comments upon practitioners of the new school.

Over a third of the book is devoted to derangements of the alimentary canal, and no reader can fail to obtain many a useful hint with regard to its minor ailments. The usual space is given to the subject of biliousness (a favorite topic with English writers), and American readers may be somewhat amused at finding that the liver is made subject to slight atmospheric fluctuations. Under the section on inflammation Dr. Beale makes a long and interesting digression into paths more strictly scientific than he had previously followed, and discusses the latest views on vasomotor nerve action. He takes occasion, moreover, to introduce his theory of bioplasts, opposing Lister's ideas on sepsis.

To commend this little book briefly, we would say that it deserves a place in the library, not so much for its intrinsic value, or because it presents any new facts, as for its suggestiveness. It is a valuable lesson which Dr. Beale teaches, that we may dignify by scientific study what is apparently of small importance, and that he only is an accomplished physician to whom no ailment is trivial.

BOOKS AND PAMPHLETS RECEIVED.

The International Encyclopædia of Surgery. A Systematic Treatise on the Theory and Practice of Surgery by Authors of Various Nations. Edited by John Ashurst, Jr., M. D., Professor of Clinical Surgery in the University of Pennsylvania. Illustrated with chromo-lithographs and wood-cuts. In six volumes. Vol. III. New York: William Wood & Co., 1883. Pp. xxxix-760.

Working Bulletins for the Scientific Investigation of the Newer Materia Medica. A Plan to Promote Progress in the Science of Pharmacology, etc. Vol. I. Detroit: Parke, Davis & Co., 1883. Pp. xv-207.

The Microscope and its Revelations. By William B. Carpenter, C. B., M. D., LL. D., etc., Corresponding Member of the Institute of France, etc. Sixth edition, illustrated by twenty-six plates and five hundred wood engravings. Vol. I. New York: William Wood & Co., 1883. Pp. xi-386.

On the Pathology of Bronchitis, Catarrhal Pneumonia, Tubercle, and Allied Lesions of the Human Lung. By D. J. Hamilton, M. B., F. R. C. S. E., F. R. S. E., Professor of Pathological Anatomy (Sir Erasmus Wilson Chair), University of Aberdeen. With illustrations. London: Macmillan & Co., 1883. Pp. xii-248.

THE
NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

Published by
D. APPLETON & Co.

Edited by
FRANK P. FOSTER, M. D.

NEW YORK, SATURDAY, MAY 19, 1883.

THE EXPEDIENCY OF THE ACADEMY OF MEDICINE'S
RECENT ACTION.

LAST week we gave a number of extracts from the legislative acts by which the Academy of Medicine was constituted, and from which it derives its powers, together with several passages from its constitution and by-laws, accompanied by a few comments in which, while conceding the entire right of the Academy to take the course it took in adopting Dr. Flint's resolutions, we remarked that the question of the wisdom of that course was quite another matter.

We hear occasionally of a tradition to the effect that the Academy was organized in great measure as a means of raising the profession of New York from a state of laxity into which it had fallen in regard to the matter of ethics. It may be that such an idea was uppermost with the founders of the Academy at the time of its organization, but whether that was the case or not is a matter of very little consequence to the present generation; the Academy long ago ceased to be the body to which the great majority of its members looked to see any prominent stand taken in ethics, for in this community those matters have by common consent been relegated to the county and State societies, and the Academy has come more and more to be looked upon as our leading scientific organization and as the central repository of the literature that belonged to the profession in common. During the last few years the Academy has made most notable and gratifying progress toward the attainment of a material prosperity and usefulness of which we might well feel proud. Year by year this fact has been realized by an increasing proportion of the profession in New York, and the feeling has been growing that every member of the profession who was so situated as to be able to contribute to the maintenance and the advancement of whatever tended to enhance the scientific resources and the dignity of medicine in New York could do so in no more fitting or effective way than by joining the Academy. In other words, a continued increase of its membership has seemed desirable and even essential to its successful working. Unless the feeling of the Academy has been grossly misinterpreted, it has itself assumed the attitude of agreement with this general sentiment.

Now, however, the Academy has distinctly proclaimed that it will not tolerate accessions to its ranks save from among those who hold certain opinions as to ethics. A less radical measure would have answered the purpose if the prime consideration was to appear before the profession throughout the country at large as dissenting from the ethical stand lately taken by the State society, for a resolution simply declaring

the sense of the Academy would have accomplished that. There can be no doubt that such a resolution could have been passed at any meeting, notice having been given previously that it would be brought up at that meeting. Such a course, while it would have been quite as emphatic an expression of ethical sentiment as was involved in the passage of Dr. Flint's resolutions, would not have crippled the Academy by restricting the number of those from whom future increments of its membership were to be drawn, nor would it have excited the pronounced feeling of regret with which many now look upon the action that was taken—a regret, it must be conceded, that has but little to do with men's sentiments concerning the ethical question.

The advocates of the code of ethics of the American Medical Association have gained absolutely nothing, so far as we can see, by this action, and it seems impossible that the Academy should not prove a heavy loser. The prospect of its adding to its membership seems exceedingly slender, since it positively declines to accept men who do not favor the re-enactment of the old code, and since those who do favor that measure are likely to be cautious about allowing their names to come before a meeting of the Academy, lest a spirit of retaliation should prompt the opponents of the old code to muster in sufficient force to prevent their election. Whatever assurance may be given that the minority will not descend to that sort of tactics, however pardonable such a course might be thought under the circumstances—and we feel sure that they will not adopt so paltry a policy—human nature is so constituted that a blow deserved is a blow feared, and so, we repeat, it is very likely that considerable time must elapse before the dominant party in the Academy can feel itself safe in bringing candidates' names before the meetings, even if the candidates themselves are willing to run the risk involved.

In a certain sense the Academy is paralyzed for the time being, and nothing short of an absolute reversal of its recent action can restore it. Such a reversal we look to see accomplished in one way or another, in spite of the pains that were taken to make the adoption of Dr. Flint's resolutions final. An attempt to restore the *status quo* would not be entered upon as a step in the ethical controversy, but solely in the interest of the Academy, and we believe it would find its most active supporters among those who are really in favor of the old code, the great majority of those gentlemen being, if we may judge by their conversation, heartily sorry that the resolutions were passed.

THE MEDICAL SERVICE ON BOARD ATLANTIC PASSENGER
STEAMSHIPS.

In our issue of March 24th we called attention to the ingardliness of steamship owners in the matter of the remuneration and quarters they allowed the medical officers of their ships, and we expressed the hope that the profession in this country would co-operate with their brethren in England in the endeavor to bring ship-owners to a sense of their

duty. We subsequently published the propositions bearing on the subject that were laid before the British Board of Trade by the Parliamentary Bills Committee of the British Medical Association. It has been our intention to publish also several communications that have appeared in our London contemporaries, especially those by Dr. J. A. Irwin, who has borne the brunt of the contest with ship-owners over the matter; but lack of space has prevented us.

We have lately been favored by Dr. Irwin with a pamphlet containing several of his letters, together with a resolution passed by the Manchester Medico-Ethical Association, leading articles from the four weekly medical journals of London, extracts from various non-medical papers, and vigorous passages from letters by Medical Director T. J. Turner, of our navy, and Dr. Morell Mackenzie, of London. In a private letter Dr. Irwin justly intimates that the American people are really more affected by the quality of the medical service on board the great Atlantic passenger-ships than his own countrymen. This, certainly, can not be denied, and we would again urge the matter upon our readers' attention, trusting that, so far as in them lies, they will co-operate with the efforts of our English colleagues to bring the service under proper regulation, and to secure for those of our profession who follow the irksome life of a ship's surgeon the comforts, the emoluments, and the authority that a medical officer charged with such grave responsibilities is unquestionably entitled to.

OLIVER WENDELL HOLMES.

Two books lie before us, of each of which it may be said that its appearance is most timely. It is but a few weeks since a few of us in New York represented in Dr. Holmes's presence the feeling of the great body of the profession that he had taken leave of—a feeling of regret that in a certain sense we were losing him, mingled with the feeling that, in the exclusive devotion to literature that he was entering upon, something of the added radiance that was sure to come to him would be reflected upon the guild that gave him his early training. This regret and this expectation will severally be emphasized in the heart of every physician who reads the volumes to which we refer.

One of these books* is a new edition of a collection of medical essays published by Dr. Holmes more than twenty years ago. It includes his "Homoeopathy and its Kindred Delusions," "The Contagiousness of Puerperal Fever," "Currents and Counter-currents in Medical Science," "Border Lines of Knowledge in some Provinces of Medical Science," "Scholastic and Bedside Teaching," "The Medical Profession in Massachusetts," "The Young Practitioner," "Medical Libraries," and "Some of my Early Teachers." The essay on the "Mechanism of Vital Actions" has been omitted—not suppressed, but transferred to a separate collection of essays.

The author's renown in general literature has for many

* "Medical Essays, 1812-1882." By Oliver Wendell Holmes. Boston: Houghton, Mifflin & Co., 1883. Pp. x+445.

years so overtopped his position in medicine that few, especially among the rising generation, have been accustomed to couple his name with the advancement that has taken place in medical science. Such a reminder as this volume constitutes was needed, therefore, to make the younger members of our profession realize how great and many-sided a man they might truly claim as their colleague by a title more emphatic than the common possession of the degree of M. D. But it is not on this ground solely that we welcome the appearance of the book; apart from the matter of sentiment, its substance has such a positive scientific value that no man who wishes to master the subjects it treats of can fail to profit by reading it. Indeed, we know of but few works better calculated to temper and refine the realistic results of the methods of medical study now in vogue.

Scarcely less to be prized by men of our profession, although not so strictly medical in its scope, is the second of the two books to which we have alluded.* Those who have known Professor Holmes only by his contributions to general literature can hardly have failed to feel a desire to know more of the man, of his origin, of his career, of his personal experiences, than he has chosen to unfold in his own productions. How much greater must that desire be with us of the medical profession, seeing that he has been of our number, and that he now goes forth from among us, yet not, we may fondly say to ourselves, wholly cut adrift from us!

Mr. Kennedy's delightful portrayal of Professor Holmes as a literary man and as a student and teacher among those of our craft comes as a fitting complement to the second view now given us of Holmes's actual work in medicine.

PROFESSOR CHANDLER, THE BUTCHERS, AND THE BOARD OF ALDERMEN.

WHEN Professor Chandler lately allowed it to be understood that he was willing to serve another term as a member of the Board of Health, the general feeling among the profession in New York was that of satisfaction that a gentleman so conversant with sanitary administration and so energetic as he had shown himself to be might be secured to continue the work of the Board of Health in the manner that has in the main heretofore characterized its action. This feeling was mingled with forebodings, however, that Professor Chandler's renomination, in case it should please the Mayor to make it, would not suit our fastidious Board of Aldermen.

We regret to have to record that these forebodings have been justified. Last week Professor Chandler's name was sent in by the Mayor, and the Aldermen promptly rejected it. Such a thing has been conjectured at one time and another as that a subtler influence than anxiety to promote the public welfare occasionally played a part in determining the actions of the Board of Aldermen, and we have heard it hinted that such was the case in this instance. To be explicit: it is said

* "Oliver Wendell Holmes: Poet, Litterateur, Scientist." By William Sloane Kennedy. Boston: S. E. Cassino & Co., 1883. Pp. 356.

that the butchers some time ago vowed that they would use their influence with their friends in the Board of Aldermen to defeat Professor Chandler's confirmation. Their grievance was, that he had insisted that cattle should not be driven through any of the city streets. In spite of their bloody calling, butchers are ordinarily a kindly set of men, not given to scheming or to brooding over injuries—even so gross an injury as an official impediment to the pastime of allowing wild steers to run amuck in the streets. That they should have so belied their distinguishing trait of jolly benignity in this matter calls to mind the old question: *Tantane animis celestibus ire?*

THE PENNSYLVANIA STATE SOCIETY ON THE NEW YORK STATE SOCIETY.

THE pointed resolutions adopted at the recent meeting of the Medical Society of the State of Pennsylvania, which we publish in another column, coupled with the fact that the mover of the resolutions was made president of the Pennsylvania society for the ensuing year, show that there is no abatement of the feeling of opposition with which our friends in Pennsylvania look upon the attitude of the Medical Society of the State of New York on the code question. Of like purport were the terms in which the outgoing president saw fit to speak of the matter in the presence of an assemblage made up in great part of non-medical persons. It is to be noted that the ethical question was not discussed on its merits, but that the act of "rebellion" against the American Medical Association was held up to execration.

Proceedings of Societies.

NEW YORK SURGICAL SOCIETY.

A STATED meeting was held April 10, 1883, T. M. MARKOE, M. D., President, in the chair.

RUPTURE OF THE TENDON OF THE QUADRICEPS EXTENSOR CRURIS ON EACH SIDE.—Dr. L. A. STIMSON presented a patient with the following history: He was a rather small, spare man, fifty-eight years old, who had always been healthy. Ten years ago he slipped while walking, fell backward to the ground, and found himself unable to use his right leg. He had broken the tendon of the quadriceps, apparently at its junction with the patella. The knee became at once painful and swollen, and he remained unable to walk for four weeks. During the following six months he walked with a cane, and noticed disability of the limb when going up or down stairs, finding himself unable to support his weight upon it when the knee was partly flexed. After the expiration of the six months he discarded the cane, and considered the limb about as good as ever; he could carry a load of from fifty to seventy-five pounds upstairs in the usual way, taking the steps with each foot alternately, and not aiding himself with his hands. He says the appearance of the knee differed from what it was before the injury; that there was a depression above the patella, and the anterior edges of the condyles were prominent.

Three years afterward (1876) he broke the tendon of the left quadriceps by a similar slip and fell backward. It was

treated in the Chambers Street Hospital by rest in bed, with the limb bandaged upon a posterior splint. The knee was swollen and painful for three weeks, and more or less stiff for six months afterward. Then he resumed work as a porter, and worked steadily until January, 1883, his right leg being all this time stronger than the left. His duties frequently required him to carry loads of from fifty to one hundred pounds on his shoulders. In walking, he kept the knees almost perfectly straight, and occasionally he fell heavily, this happening whenever he slipped and bent the knee. In going up and down stairs, he always aided himself with his hands on the banisters; he says he was always fearful lest he should fall, yet he carried weights, and even climbed ladders. He could not rise from a sitting posture without aid unless the seat was so high that the knees were extended.

Early in January, 1883, the right knee joint suppurated from unknown cause, and he entered Bellevue Hospital. The joint was opened in the median line above the patella, drained, and immobilized. The discharge ceased about the end of February.

His present condition is as follows: *Left Knee.*—When the knee is flexed nearly to a right angle, the anterior surface and edges of the condyles are very prominent, and the patella lies below, leaving a deep sulcus above it between the condyles occupied only by skin and cellular tissue; this skin is rather closely bound to the condyles, so that it does not move upward so freely as the patella. The patella can be raised from the condyles, and the finger pressed between it and them from above to the distance of nearly an inch by pushing the skin before it. The quadriceps is atrophied to such an extent that the femur seems almost subcutaneous in front.

The power of active extension is entirely lost. Even when the leg is hanging straight down, with the knee slightly flexed, the foot can not be moved forward in the least, except by swinging it.

Right Knee.—Still somewhat swollen, and the soft parts indurated. The patient says that its appearance before the supuration in January last was almost exactly the same as that of the left knee. The quadriceps is not so completely atrophied as the left, and the patient says the right has been the better limb of the two.

He walks now with one crutch, taking short steps.

Dr. R. F. WEIR said that he had just finished treating such an injury in a very heavy man who tumbled in the usual way without striking his knee, but the rupture was different from that illustrated in Dr. Stimson's case. He had met with two varieties of ruptures: one where the tendon was torn entirely across, and the other where only the central portion was ruptured. In his recent case the central portion was involved, and, by drawing the muscle down by strips of rubber adhesive plaster and immobilizing the joint, he was able to get a very good result, so that the patient was able to throw the leg forward and go upstairs without difficulty. He had seen, a few years ago, one case in a woman where the tendon was apparently divided completely across, but there was some power of extension, showing that it was not entirely separated.

In cases of ruptured quadriceps, attempt had been made to reunite the parts by sutures under antiseptic precautions, but the results had not been sufficiently encouraging to warrant repeating the operation. Better results and greater security had been obtained by immobilizing the joint with the posterior splint.

Dr. LEROY M. YALE had seen a case in which the tendon had been torn and the patella dislocated laterally by the limb being caught between a cask and the side of a house. The use of the limb was impaired as long as the gentleman lived. The patella,

however, made for itself a new point of adhesion at the side of the joint, and the condyles were exposed by so much as the patella had been displaced by the dislocation.

Dr. CHARLES T. POORE remarked that he had already reported a case to the society in which rupture of the quadriceps had taken place, and the separation was four inches, which was finally reduced to about three inches. The rupture was complete. The ultimate result was that the patient had perfect use of the limb (flexion and extension), and walked without a limp.

EPITHELIOMA OF THE EYELIDS, NOSTRIL, AND SIDE OF THE FACE.—Dr. A. G. GERSTER presented a patient, sixty-four years old, illustrating the final result of the removal of an extensive epithelial cancer which had its commencement at the outer canthus of the right eye. The disease had gradually, in the course of several years, involved the upper and lower eyelids, the entire conjunctiva, a considerable portion of the superior maxilla, the cheek, and the right nostril. When the patient first came under his observation, in September, 1881, Dr. Gerster, with a great deal of difficulty, succeeded in exposing the eye, and found the cornea ulcerated and in part covered with cicatricial tissue. The patient was entirely unable to move the eyeball, and Dr. Gerster suspected involvement of the orbital tissue. The patient insisted on getting rid of this offensive ulcerating mass, and, when Dr. Gerster had made the necessary incisions, he found that the tissues occupying the posterior portions of the orbit were not involved at all. The case, therefore, was not so hopeless as it seemed to be before the orbit was opened. The eye, all the orbital fat, a portion of the superior maxilla, a part of the skin of the cheek and forehead, both eyelids, and a portion of the right nostril were removed. The defect following the operation was enormous, and it was very incompletely repaired by the process of cicatrization and contraction; and finally, in January, 1882, he proposed a plastic operation with a view to remedying the disfigurement as far as possible. To do this he raised two large flaps from the forehead, using one for the formation of the lower eyelid and cheek, and the other for the formation of the right nostril. He cut both flaps intentionally in an oblique direction, in order to make them as long as possible. A small part of the flap out of which the nostril was formed sloughed on account of the pressure of the adhesive-plaster plug placed in the newly formed nostril, which, however, looked very satisfactory.

Having obtained union of the two flaps, he still had considerable redundant pedicle. The redundant part of the pedicle used for the nostril was separated three weeks after the former operation, and, being attached by sutures to the skin of the forehead, served to form an upper eyelid. This subsequently was drawn deep into the orbit, thus forming a sort of lining for the roof of the cavity, and the cicatricial contraction thus exerted had the effect of smoothing off the unseemly protuberance caused by the rotation of the pedicle. The redundant tissue of the other flap was also cut away and put back into the defect caused by its original removal, where it helped to hasten the final healing of the wound. The ghastly deformity having been reduced to a small granulating space occupying the apex of the orbit, the patient was enabled to get along well with the aid of a small bit of black silk placed over the orbit as a protector. So far, no relapse of the disease had appeared.

THE WEAK POINTS IN A LISTER DRESSING, AND THE ADVANTAGES OF COBORSIVE SUBLIMATE AS AN ANTISEPTIC.—Dr. ROBERT F. WEIR read the following paper:

It must be admitted by the most devoted of the advocates of Listerism that the dressings, applied with the strictest attention to all the details of this system, not infrequently fail in controlling the progress of putrefaction. This is the case not

only in a severely lacerated wound, but also, at times, in a comparatively simple one. It is difficult in all cases to explain why this should be so; in some, no doubt, some error in the technique may have been committed by the surgeon himself; in certain other cases it must be assumed either that the antiseptic itself, i. e., the carbolic acid, is at fault, or has been wrongly applied, or that the dressings themselves are imperfect in construction. In connection with these two points considerable vagueness has been encountered. According to Mr. Lister, who started with a solution of one part of the acid to 100 parts of water, the solutions to be employed now are, for the instruments, hands, etc., 1 part to 20; for the spray, 1 to 30; and for the sponges, etc., 1 to 40. Why should such diversity exist? What strength, in other words, is necessary to arrest or destroy bacteric life in a wound? Clinical experience has generally settled on the range of strength given by Lister, to wit, two per cent. to five per cent. of the acid. But the application of laboratory tests does not apparently accord with this conclusion. For instance, in an article by De la Croix,* it is stated that ten per cent. of carbolic acid is required to destroy bacteric life, and, in the very careful and much to be admired investigations of Koch (Koch, p. 242), it is likewise recorded that ten-per-cent. solutions of carbolic acid are necessary for safe or sure disinfection, and that the anthrax spores are destroyed in a forty-per-cent. solution only after three days, and in a five-per-cent. solution only after two days' immersion. These statements have been widely quoted, and have much embarrassed observers by their variance with clinical work. But, on reference to the articles themselves, and particularly to that of Koch "On Disinfection," published in the reports of the Imperial Board of Health for 1881 ("Mittheilungen aus dem kaiserlicher Gesundheitsamte," Berlin, 1881), there will be found a reason for the discrepancy. It consists in this, that the experiments have purposely been conducted upon the *spores* of the anthrax bacillus as being the most resistant to disinfectants of all such micro-organisms. These spores are much more difficult to affect than the bacilli themselves. To show the influence of weaker solutions upon the bacilli themselves, a number of tests were applied by Koch by soaking silk thread in the juice expressed from the spleen of a mouse affected with anthrax bacilli, and then wetting them with one-, two-, three-, and five-per-cent. solutions of carbolic acid for periods varying from two, five, ten, fifteen, to twenty-five minutes. After these had been placed in a gelatine culture-glass no signs of development occurred, showing that all life had been arrested. In the central preparation, however, of the same impregnated threads which had not been dipped in the carbolic solutions, there were to be found in the gelatine culture-glasses marked development of bacilli, and even of spores. Again, a one-per-cent. solution of carbolic acid, with an equal quantity of anthrax blood, injected into a second animal, proved innocuous, but a one-half-per-cent. solution failed to neutralize the poisonous blood. Similar observations were carried on in respect to less obdurate micro-organisms, including the micrococci found in septicæmia; and, from a large experience gathered in this manner, Koch formulates the statement that carbolic acid in one- to five-per-cent. watery solutions is a good disinfectant for those organisms which have not passed into the *dormant form* or the condition of *spores*, and that 1 part to 400 of water—i. e., one quarter per cent.—must be *permanently* present to control life in the bacteria met with in wounds. Note carefully here the use of the words "permanently present," and it must also be remembered that to produce this condition stronger solutions are of necessity to be employed.

More recently these experiments have been repeated with a

* Arch. f. Pathol., Bd. xii, Heft 3 and 4, 1881.

corresponding result by Dr. Sternberg, United States Army ("Experiments to determine the Germicide Value of Certain Therapeutic Agents," *G. M. Sternberg*, "Am. Jour. of the Med. Sci., April, 1883"), who has found, by the test of flask culture in reference to carbolic acid, that a 0.2-per-cent. solution of this acid would so act upon septic micrococci as to prevent development, but that a stronger solution was required for the micrococcus of ordinary pus. This observer, reiterating the remarks of Koch that the resisting power of reproductive spores is far greater than that of bacterial organisms in active growth (multiplication by fissure), says that the quantity of carbolic acid to be used as a germicide should not be less than five per cent., for it is necessary, he wisely states, to keep on the safe side, since we do not know whether all of the pathogenic bacteria form spores or otherwise.

These considerations, which might be extended by detailing more at length the steps of the various experiments, or by quotations from other observers, are sufficient to explain the satisfactory results that follow the present use of carbolic acid in the treatment of wounds, and to show us that the antiseptic has in the main hitherto been rightly used. In looking further for the causes of error, some may, perhaps, be found in the imperfection of the dressings. Tests of the strength of the gauze employed revealed to me, in January, 1880, that the strength of this part of the dressing varied much with its age. Gauze impregnated after Lister's formula, and kept in a tight box wrapped up in rubber cloth, gave, at the end of three months, 1.44 per cent. of carbolic acid, and another specimen, similarly prepared and preserved, showed, at the end of three weeks, 1.82 per cent. These observations have been confirmed by Kopff, who found, on the second day after gauze had been impregnated according to Lister's and Bruns's method, that the former contained 2.61 per cent., and the latter 5.62 per cent. In the gauze sold in the shops only 0.5 per cent. of carbolic acid was found. The gauze, when used, therefore, should be freshly prepared, for which purpose Bruns's formula is the best. (Resin, 400 gr.; carbolic acid, 100 gr.; castor-oil, 80 gr.; alcohol, 2 litres.) Another possible cause of failure in antiseptic dressing is encountered in the catgut ligature. Made, as it is, from the intestines of a sheep, it is not to be wondered at that the possibility of infection thereby should have been considered. Few, however, have been the facts that confirm such a suspicion. Koch calls attention to this, and De Lanti ("Arch. gén. de méd.," March, 1883) more recently repeats this caution, and quotes Zweifel, of Erlangen, who believed the catgut to be a cause of infection in wounds. Koehler, of Berne, also furnishes a case where apparently the septicæmia was due to this cause, and Volkmann reports two cases of malignant pustule from the inoculation by means of anthraxis catgut ("Deutsche Zeitschrift f. pract. Med.," No. 18, 1877). In investigating this point, Koch has proved, by careful experiment, that solutions of carbolic acid in oil or alcohol are absolutely inert in respect to their action on bacteric life, either on the spores or bacilli. He took solutions of one and five per cent. carbolic acid in oil, also pure oil itself, and tested them with the anthrax bacilli and other micro-organisms, and proved that bacteric life was arrested in the pure oil at the end of six days; the same took place in each of the carbolized solutions. The same, moreover, occurred in the experiments when the bacilli were exposed to the air on gelatine. In other words, no influence was exerted by carbolic acid when mixed with oil. The bacilli lived as long in oil and oily solutions as in the conditions of culture. When the spores, however, of the anthrax bacillus were introduced in the carbolized-oil solution, reproduction could be accomplished after three months' immersion. The same results were met with in oily solutions of thymol and salicylic acid. In explanation of the antiseptic action of carbolized

oil as a wound dressing, Koch, however, remarks that, "when it came in contact with substances containing water, as, for instance, the tissues of the human body, wounds, etc., then it undoubtedly gave up part of the acid to these, and in this way an antiseptic effect might be obtained. But this holds good only in cases where aqueous fluids came in contact with the oil. In all other instances where dry substances, such as silk, catgut, instruments, etc., are to be disinfected by carbolic oil, not the least antiseptic effect is to be expected even upon the most vulnerable micro-organisms." These investigations, it may be added, have been fully confirmed by those of Wolfhügel and Knowe in the same volume of reports. Koehler, of Berne (already quoted), also made sundry experiments bearing on this point. This surgeon placed ordinary catgut, with all the customary precautions, in sterilized fluids, which became turbid from bacteric development within twenty-four hours. He also found that if the catgut was steeped for twenty-four hours in the oil of juniper, and kept in 95 per cent. alcohol, it would not develop bacteria in sterilized fluids. I do not know of any experiment that will determine whether the chromic acid used to render the catgut ligatures more durable makes them at the same time antiseptic; but we have information relative to sulphurous acid which will be somewhat startling to the surgeons in this city who have relied upon this gas as a proper disinfectant for their contaminated hospital wards. Two investigators, Koch and Wolfhügel, pronounce decidedly against sulphurous acid in gas and in watery solution as a disinfectant, i. e., as an arrestor of bacteric life. Koch says no real value can be claimed for it, and in none of the experiments instituted with it did it succeed in destroying all the germs present. The reliability of the tests of Koch and his assistants should attract attention to this point, as not only is this agent largely employed here in hospitals as above alluded to, but it is likewise recommended to the public by our health boards for disinfection after scarlatina, diphtheria, and other contagious diseases. I may remark, in passing from this portion of my subject, that the most reliable disinfectant for closed spaces was found in bromine, and ranking a little lower was the less expensive chlorine.

Returning to the catgut, it must be admitted that while thus open to the suspicion of a septic, yet the daily experience of surgeons has taught that its principal defect was in its unsatisfactory insolubility. Since the addition of chromic acid and sulphurous acid to it, its durability in the tissues has been too much increased, and though the latter acid has permitted the catgut to be kept in a dry state, and the oil thus avoided, yet I have found that it will not dissolve for from twenty to thirty days, and that it acts often as a foreign body. Weakening both the acids has improved it somewhat, but my experience in this line has not been sufficient to speak yet with positiveness.

The probing of scientific research has in this way revealed to us some of the weak points of the carbolic dressing. But, notwithstanding this and the earlier condemnation of the spray by Trendelenburg, Bruns, Mikulicz, Wernich, Duncan, and others—a verdict which is, however, not accepted by Lister, Nussbaum, Rydygier, Shiene, and their followers—Lister's dressing has remained until very recently the best for surgeons to employ, though other antiseptics, notably iodoform, have given very satisfactory results in other hands. The volatility of the former antiseptics and the toxic properties of both those named were decided disadvantages.

Very lately an old remedy has appeared in this rôle as an antiseptic. This is the corrosive sublimate, or the old bichloride of mercury, the mercuric bichloride of the new nomenclature. My first experience with this salt as a wound dressing was obtained after reading an excerpt from the article of De la Croix, in which it was stated, that corrosive sublimate in the propor-

tion of 1 part to 2,525 parts of water was an efficient germicide, being 250 times more powerful than phenol or carbolic acid. With these imperfect data, I used it in the spring of 1882. I used it in 1 part to 2,000 of water as a dressing to three compound fractures of the thigh, and six of the leg, with very satisfactory results; so much so that, when I resumed my service in the New York Hospital in November last, the dressings were continued, but with some slight modifications. These were, first, that it was found that the strength was insufficient, active bacteric life being at times found under the dressings, and also from the fact that a perusal of the large experience of Kümmel and Schede, of Hamburg, showed that a stronger solution was required, and that it was free from the risk of toxic effects, for, in over 200 cases presented by Kümmel, in only 2 were there any constitutional symptoms observed, and then only a slight salivation. This surgeon says of the sublimate dressing, that the healing of wounds is accomplished with a certainty and uniformity unknown under the strictest Lister dressing; and in 212 extensive wounds as recently treated by the sublimate solution and peat dressing by Esmarch and Neuber, who recommend it strongly, there was no poisoning, and only three deaths. In the number were 30 major amputations, 32 resections and osteotomies, 5 herniotomies, 14 cases of nerve stretching, etc. In only 11 cases was the dressing changed more than once. Bergmann, whose experience with this remedy has also been large, also lauds it. My own observation of the efficacy of the sublimate dressing after I had properly achieved the correct method of using it is but comparatively slight, embracing four cases of necrosis of the foot and tibia, one amputation at the hip joint, one amputation of the thigh, one amputation of the leg, one amputation at the knee, one amputation of the breast, two removals of tumors, one fixation of a movable kidney, one extensive laceration on upper thigh (death on the twelfth day of septicæmia), one subdeltoid bursa, three compound fractures of leg, with recovery excepting the one above noted. In two of the compound fractures an aseptic condition was not preserved. In one of these the solution was too weak—1 in 2,000. In the other a 1-400 peat dressing was used, although by error solutions of 1-100 were several times resorted to. No special local effects were produced beyond in one instance slight pustulation of the adjacent skin. No constitutional effects were noticed in any case.

Let me hastily indicate the mode of employment of the dressing. Carbolic-acid solutions are used by Neuber, Kümmel, and Bergmann for the spray and for the instruments, and sometimes for washing out the wound. The sponges and compresses are wet with a solution of the sublimate, 8 grains to the pint (solution No. 1). Silk, if used for sutures, etc., is dipped for two hours in an 80 grain to the pint solution, and then permanently kept in the 8-grain solution. Catgut, as used by Kümmel, is made by immersing it in an 80-grain solution to the pint for twelve hours, and then is wound on bobbins and kept in an alcoholic solution of 20 grains to the pint, with one ounce and a half of glycerine added.* The gauze is prepared by immersion in a solution of 20 grains to the pint of alcohol and one ounce and a half of glycerine. Drainage is accomplished by rubber tube or by spun glass, twisted or plaited. If sand is used as an absorbent, after being heated in a crucible, it is mixed in the proportion of one pound to one drachm of sublimate, dissolved in two ounces and a half of sulphuric ether. The sublimated sand is put in bags of various sizes, from 12 to 40 centimetres

square, which have previously been washed in green soap and soda, rinsed, and finally dipped in the 8 grain to the pint solution. Peat, saw-dust, and other absorbents are also employed* according to the judgment of the surgeon. It has been found in my wards that while pine saw-dust has absorbed readily, yet a disagreeable sour odor was often noticed, even when the underlying wounds were doing perfectly well.

A few words more will complete these necessarily incomplete remarks. The experiments of Koch evidently excited the surgeons of Hamburg, Würzburg, and Kiel to the use of the mercuric bichloride as a surgical dressing, and, as the results of this able investigator have not been very widely disseminated on this side of the Atlantic, I beg to summarize them here. After applying a number of tests similar to those employed in connection with a number of so-called antiseptic disinfectants (a partial list of which is here appended), he found that simply moistening the anthrax spores (the most resistant of all, it will be remembered) in a solution of 1 part of corrosive sublimate to 5,000 of water destroyed them thoroughly and immediately, and the destruction would equally happen if they are immersed for a longer time in solutions as weak as 1 to 20,000. He then says that the sublimate is the only known disinfectant which succeeded, by a single application of a few minutes of a solution of sublimate of 1 part to 1,000, in destroying the most resistant micro-organisms. He also furnishes us with a test as to the strength required in a wound dressing. There should be present in a dressing an excess of corrosive sublimate equal to 1 part to 5,000. This will be readily recognized by leaving a thin strip of polished copper for half an hour in the dressing. If the excess is present, an amalgam will show itself. This seldom occurs in a 1 to 10,000 solution.

Naturally, with so potent a bacteric arrestor, the idea comes into birth, Can not the internal administration of this remedy be utilized in germ diseases? Koch's experiments in anthracised rabbits by injecting sublimate solutions, however, were negative. Sternberg, estimating the blood in an adult of one hundred and sixty pounds to be twenty pounds, ascertained that the quantity of corrosive sublimate required to affect this amount of blood would be 3.5 grains. I believe that, although one grain per diem is the maximum quantity which could be administered for several days, a cumulative effect might be produced by its use sufficient to exert some restraining influence on the development of micro-organisms when in the system.

Taken from Koch and Sternberg's papers, the annexed tables give an interesting *résumé* of the germicidal power of a number of agents, some of which have wrongly been relied upon:

TABLE I. (From Koch—"Mittheilungen aus der kaiserlichen Gesundheitsamte," Berlin, 1881.)

Corrosive sublimate, 1 per cent. in water, destroyed all bacteric life in.....	1† day.
Potassium permanganate, 5 per cent., destroyed all bacteric life in.....	1† day.
Potassium permanganate, 1 per cent., no effect at end of.....	2 days.
Osmic acid, 1 per cent.....	14 days.
Turpentine, oil of.....	50 days.
Chlorine water, freshly made.....	14 days.
Bromine, 2 per cent.....	14 "
Iodine water.....	14 "
Chloride of lime.....	50 days.
Chloride of iron.....	64 "

* The Catgut dissolves too quickly in a wound; since recently proved more satisfactory. When after the corrosive impregnation had been secured, the gut was dipped for two hours in a 1-1,000 chromic acid, then dried, and kept in this state for use.

* The absorbing power of turf is 50 parts water; saw-dust (pine), 55 parts; cedar, 44; tan, 23; sand, 14.

† Life destroyed totally.

Iodine in alcohol, 1 per cent., hindered growth only.	
Arsenic, 1 per cent.....	16* days.
Sulphurous-acid water, very slightly efficacious.	
Sulphuric acid, 1 per cent., growth hindered in....	10 "
Quinine, 1 per cent.....	10* "
Boric acid, 5 per cent., practically unreliable; spore growth only hindered in.....	6 "
Borax, 5 per cent., no effect at end of.....	15 "

TABLE II. (From Sternberg.—"Am. Jour. of the Med. Sci.," April 1883.)

VALUE OF GERMICIDE.

Mercuric bichloride, 1 part in.....	20,000
Potassium permanganate, 1 part in....	833
Iodine, 1 part in.....	500
Cresote, 1 part in.....	200
Sulphuric acid, 1 part in.....	200
Carbolic acid, 1 part in.....	100
Hydrochloric acid, 1 part in.....	100
Zinc chloride, 1 part in.....	50
Tincture of chloride of iron, 1 part in.....	25
Salicylic acid dissolved by sodium borate, 1 part in....	25
Boric acid, no value.	
Sodium borate, sat. sol., no value.	
Sodium hyposulphite, no value.	

Dr. GEESTER said he had used ligatures prepared after Kocher's method, by the use of oil of juniper, almost exclusively since September, 1882, and in not a single case had suppuration undoubtedly been caused by the ligatures. So far as manipulation of the material so prepared was concerned, it was very agreeable to handle. It was hard and firm, especially if it had been kept for some time in ninety-five per cent. of alcohol, which apparently had the effect of toughening the substance; it tied very nicely, and was not absorbed too soon. He had used it for ligating the large vessels, and with excellent results. As a suture it answered very well, and lasted longer than the carbolized suture of Lister.

He had also employed Bruns's gauze in the German Hospital, the Mt. Sinai Hospital, the German Dispensary, and in private practice. The original method of preparation by the use of alcohol as a solvent made the material very expensive, and, with the co-operation of the druggist, he finally succeeded in finding an excellent solvent in benzine, which, during the last four years, he had been using exclusively. Contrary to what was at first suspected might occur, the benzine had not affected the skin unfavorably, and the cost of the gauze prepared in this way was very considerably less.

Dr. WEIR remarked that he had made experiments four years ago with benzine as a solvent, and had found, in corroboration of the statement made to him by Dr. Squibb, that the evaporation of this solvent was so rapid that it carried off with it an undue amount of carbolic acid held in solution. Therefore, the gauze and jute prepared with benzine very rapidly deteriorated, and it gradually fell into disuse in the New York Hospital and other institutions where it had been employed.

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held March 6, 1883, Dr. C. C. LEE, President, in the chair.

The minutes of the previous meeting were read by the secretary and approved.

COMBINATION OF HARD AND SOFT RUBBER PESSARY.—Dr. J. B. HUNTER presented the instrument, which consisted of an upper soft rubber bow attached to the lower portion, which was made of hard rubber, thus combining the advantages of elasticity in

the former with the innoxious qualities of the latter. Hard and soft rubber could now be welded perfectly.

PLASTER-OF-PARIS PESSARY.—Dr. B. F. DAWSON stated that he wished to record that he had made use of plaster of Paris, molded within the vagina, with the most decided success, in two cases of displacement of the uterus. The first case was that of a woman suffering from antversion and a very aggravated prolapse of the left ovary. She was placed in the knee-chest posture, and pledgets of absorbent cotton, each with a string attached, soaked in a mixture of plaster of Paris and water of about the consistence of gum and partially squeezed out, were placed in the posterior fornix of the vagina and around the vaginal portion of the cervix, and held in position. The vagina was then cleaned out, in a few moments the cast had hardened, and the patient went away with instructions to withdraw the instrument should it cause pain. When she came back at the end of three days she said she had experienced great relief. On removing the plaster pessary, the mucous membrane with which it had come in contact, instead of being irritated, as one might have expected, was found to have been benefited by its presence; it was firmer and less irritable than before, and the prolapsed ovary had evidently been sustained. The second case was one of retroflexion, in which the pessary acted not only as a harmless agent, but seemed to give all the uterine support desired. The instruments were removed, placed in fire to burn out the cotton, and dipped into wax or paraffin for the purpose of making them impervious to the secretions and to render them more durable. This method of supporting the uterus commended itself for the facility with which it could be applied, for cheapness, and for accuracy of adaptation.

DOUBLE OVARIOTOMY, WITH FIRM ADHESIONS TO THE UTERUS.—Dr. HUNTER operated on a girl on the 5th of February for what was supposed, by himself and others who examined the patient with him, to be a single ovarian cyst, but, upon cutting through the abdominal walls, the tumor was found to be double, and firmly attached to the uterus, which lay in front of it. The contained fluid had the appearance of decomposed blood, but was not offensive. Some escaped into the peritoneal cavity, but was washed out, and the patient made a perfect recovery after a sharp attack of peritonitis. The pedicle was cauterized with the hot iron. Dr. Hunter also referred to a case, operated upon on the 24th of February, in which the tumor, which was single, was firmly attached to the uterus. The patient made a good recovery.

In corroboration of Dr. Hunter's remarks on the value of the hot-iron cautery applied to the broad pedicle, the President referred to a case in which neglect to use it was probably the cause of the patient's death. Early in October last he operated in a case in which the cyst had formed such close adhesions to the intestines and pelvic organs that its detachment was unavoidably attended by a large amount of oozing. After a double ligature was applied to the base of the cyst, the abdominal cavity was sponged out thoroughly, but within three days afterward the patient manifested symptoms of septic peritonitis, and it was decided to open the wound and remove any fluid that might have been the source of poisoning; none, however, was found. The patient died of peritonitis; but probably, had all oozing been checked in the first place by the application of the hot-iron cautery, the fatal result might have been avoided.

Dr. HUNTER remarked that a case was reported by Dr. McFarland in the last number of the "Canadian Practitioner" in which a tumor firmly attached to the uterus was torn off, causing a good deal of hemorrhage, which, however, was checked by the hot iron, and the patient recovered. Dr. Hunter considered this the best way of checking hemorrhage from wounds of the uterus in such operations.

* Life destroyed totally.

The President remarked that many years ago, before ovariotomy was extensively performed in London, Dr. Baker Brown was in the habit of making use of the hot-iron cautery in all cases, whatever other means might be resorted to for checking hemorrhage. Since his time an earnest advocate of the method was Keith, of Edinburgh. The President thought that, if it were more commonly employed by ovariotomists in this country, the percentage of recoveries would be greater. He had never known a case of recovery from laparotomy in which the persulphate of iron had been used as a hæmostatic.

Dr. DAWSON had used the heat cautery in a large number of operations of various kinds with very favorable results, and he thought one advantage which it possessed over other caustics was the fact that the vitality of the deeper tissues was not affected, and that the superficial charred surface was comparatively innocuous.

Dr. H. J. GARRIGUES remarked that Keith used the actual cautery alone, without the application of a ligature.

Dr. Garrigues reported in writing a case of labor in which the head, hand, foot, and cord presented. [It will be given in a future number of the journal.]

Dr. W. R. GILLETTE remarked that he saw nothing special to discuss or dispute in the paper presented by Dr. Garrigues. The position of the fœtus was not a unique one, and the method for its delivery was that which had been for years recommended, and which experience was daily showing to be the only proper method for relieving such cases. The practical point in the doctor's paper seemed to be a forcible reiteration of the statement that it is always better to make traction upon the foot most distant in version. By taking this foot, the child is made to describe the largest possible arc of a circle, and the danger of wedging when the near foot is taken is thoroughly obviated. This is the secret art in easy, successful version cases; and, if all obstetricians would take the time in version to seek for the foot farthest away, they would have less difficulty in version, and the dangers laid down by the old authorities in accomplishing version would be entirely obviated. Dr. Garrigues's case reminded the speaker of one, which he once saw in consultation some years since, where three medical gentlemen had been endeavoring to deliver a woman for hours, without success. The neck, right foot, right arm, and cord were presenting. The physicians in attendance had succeeded only in rupturing the perinæum and tearing the urethra, which hung in a mass beneath the pubes, resembling the clitoris, and otherwise inflicting injuries which afterward resulted in her death. They had made this same fatal mistake, and had been pulling down upon the near foot until they had so complicated the presentation that it seemed utterly impossible for them to deliver. They looked upon the case as one of monstrosity, and were certain that this was the condition which would be found. Examination proved that there was no monstrosity, but that simply the right shoulder had originally presented; and, in their attempt to deliver, they had seized the right foot and so changed the presenting part, and finally left it with the conditions as related above—namely, the neck, arm, right foot, and cord within reach of the examiner. By simply replacing the right arm, and seizing the opposite foot, delivery was accomplished without difficulty.

Simpson was the first one to lay down this rule in version; and since that time it had been the practice with most obstetricians. The philosophy of the mechanism of version performed after this method had been very accurately and vividly portrayed in Barnes's work on "Obstetric Operations."

With regard to the further point in the doctor's paper regarding the indications for the use of the forceps in such cases, he did not think any positive rules could be laid down. One

must be governed by the circumstances attending each individual case. He believed that, where the os was dilated, version was fully as safe as, and even safer than, the use of the forceps. The older writers had laid too much on stress upon the dangers of version. In the case of a decomposing fœtus, he certainly would hesitate to perform cephalotripsy until all other means of delivery had been tried and proved ineffectual.

The President believed that the dangers which attended version as pictured by the older authors must have been largely due to unhygienic conditions, for at the present day the procedure certainly was not followed by any such bad results as we had been taught to anticipate. He himself had never known it to excite metritis or endometritis.

HENRY J. GARRIGUES, M. D.,

B. F. DAWSON, M. D.,

FRANK P. FOSTER, M. D., *ex-officio*,
Committee on Publication.

MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA.

The thirty-fourth annual meeting was held at Norristown on Wednesday, Thursday, and Friday, May 9, 10, and 11, 1883. Dr. WILLIAM VARIAN, of Titusville, President, in the chair.

After an opening prayer by the Rev. Mr. WEDDELL, of Trinity Lutheran Church, the roll of delegates was called by the secretary, Dr. WILLIAM B. ATKINSON, of Philadelphia. Dr. HIRAM CORSON, chairman of the Committee of Arrangements, gave an address of welcome, alluding to historical matters connected with Norristown and neighboring places. A report by the delegates to the American Medical Association was then read. The corresponding secretary, Dr. JOHN G. LEE, of Philadelphia, read a communication from the Chester County Medical Society, setting forth a plan for the preliminary examination of persons about to begin the study of medicine. The report was referred to a special committee. The treasurer, Dr. BENJAMIN LEE, of Philadelphia, mentioned the unsatisfactory provision made for storing the society's library, and moved the appointment of a committee, with power, to provide suitable rooms for library purposes in Philadelphia. Action on the motion was postponed.

THE STATE BOARD OF HEALTH BILL.—Dr. BENJAMIN LEE, chairman of a committee charged with the matter of promoting legislation to establish a State Board of Health, reported that the committee had taken pains that the bill presented to the present Legislature should be as free as possible from all objectionable features. It was made as brief as was consistent; its provisions were general rather than specific, and the amount of expenditures which it proposed was ridiculously small in comparison with the ends to be attained. The bill was introduced into both branches of the Legislature, and the committee held personal interviews with several members of the Senate and House of Representatives. They represented the advantage of the measure to the Commonwealth, and did everything in their power to have it passed. It was rapidly making friends in both houses when an amendment was offered proposing to recognize by name and to make it obligatory on the Governor to appoint upon the board the adherents of an exclusive dogma in medicine. This was met with opposition by the medical members of the Legislature, and the bill, after being subjected to a number of amendments, was finally lost. No previous bill on this subject had received so much attention, or had been so discussed. The committee felt confident that the seed thus sown would eventually bear fruit. The report was closed by an appeal to the members of the society and of the editorial fraternity to urge the necessity of a central sanitary supervision in the State,

and the saving of health, life, and wealth which would be effected by it. If this was done, there could be no reasonable doubt that success would crown the long-continued efforts of the society. The report was received and the committee was discharged.

ETHICAL RESOLUTIONS.—On motion of Dr. HENRY H. SMITH, of Philadelphia, the following resolutions were adopted unanimously:

Resolved, That the State Medical Society of Pennsylvania reaffirm its approval of and adhesion to the code of ethics adopted by the American Medical Association.

Resolved, That organized opposition, by local societies or by individual members, to the code approved by the medical profession of the United States is rebellion against the constituted authorities, and should be so treated.

Resolved, That the secretary be instructed to forward a copy of these resolutions to the Committee of Arrangements at Cleveland, for presentation to the Association.

WRITERS' CRAMP.—Dr. BENJAMIN LEE made some remarks on the affection known by this name, insisting that a distinction should be made between the spastic and the paretic forms of the disease. He showed certain mechanical devices for the relief of the affection, one of which consisted of a ball to be held in the hand, and another of the bracelet devised by Von Nussbaum, to either of which the pen was to be attached. The latter was especially suited to cases of the cramp-like form of the affection, since its action was to call the extensor muscles into play, those being the muscles really at fault, according to Von Nussbaum.

THE DERATION OF VACCINAL PROTECTION, AND THE EFFICACY OF REVACCINATION.—Dr. WILLIAM M. WELCH, of Philadelphia, read a paper on this subject, in which, after reviewing some of the early theories as to the nature of vaccinia, remarking upon their fallaciousness, as well as upon that of the implicit trust that was formerly placed in vaccination as a complete protective against small-pox, he demonstrated the perfect trustworthiness of revaccination as a supplementary measure. Facts were presented, drawn largely from the speaker's long connection with a small-pox hospital, that told materially against Mr. Marson's doctrine of the relation of protection to the number of insertions made in primary vaccination. The sooner we ceased to rely on a multiplicity of insertions, the better; the only safeguard was in repeating the operation after an interval, especially during adolescence. During all the twelve years of Dr. Welch's connection with the Municipal Hospital, he had never observed a fatal case of small-pox in a person who had been properly revaccinated. However, the more typical the original vaccination, and in particular the slower its course, the more lasting was the protection afforded. Hence, the use of animal vaccine, or of humanized lymph of early removes, was to be preferred, because, as was well known, the vaccinal lesion produced by it was slower and more thorough in its development than the lesion that followed the employment of a long humanized stock. Nevertheless, since ample temporary protection was afforded by a vaccinal lesion that passed through its evolution rapidly, the latter was to be preferred in cases of actual exposure, when it was an object to anticipate the development of variola, and thus prevent it.

THE ADDRESS IN MEDICINE.—Dr. JAMES TYSON, of Philadelphia, then gave the Address in Medicine, on MALARIAL HÆMATURIA. After giving a well-digested *résumé* of our knowledge of the pathology of the affection, Dr. Tyson stated that in the ordinary form of the disease he preferred the simple quinine treatment as a rule, reserving the use of mercurials as an adjuvant until it was shown in any individual case that quinine alone was not sufficient. Arsenic, alone or with iron, he had not found to be of any decided advantage in cases that had re-

sisted the use of quinine and mercury; nor had he been able to accomplish much more with ergot. Benefit was to be expected from the use of many of the natural astringent mineral waters, notably those containing iron and alum. Of late years, a malignant form of malarial hæmaturia seemed to have been more prevalent than before in the Southern States. It sometimes came on suddenly, with grave icteroid symptoms, adynamia, and coma. In the pathology, however, anæmia of the viscera was dominant, rather than congestion; the jaundice was hæmatogenic; and the urinary manifestation was a true hæmoglobinuria or hæmatinuria, following on the disintegration of the blood corpuscles. In this form, too, quinine must be relied on to break the paroxysm, and it might be given hypodermically. Free stimulation was also necessary, but the use of large doses of turpentine did not seem very rational.

NOTES IN OBSTETRICS.—Dr. R. L. SIBBERT, of Carlisle, read a communication, largely of a statistical and analytical nature, embracing his personal experience in the practice of obstetrics. In a case of difficult breech presentation, after decapitating, he was obliged to resort to the use of an implement made for the occasion by a blacksmith, in order to extract the head. In one case of precipitate labor, inversion of the uterus took place.

THE ARTIFICIAL FEEDING OF INFANTS.—Dr. HUGH HAMILTON, of Harrisburg, read a paper on this subject, in which he recommended a mixture of fresh cow's milk, alkalinized with bicarbonate of sodium, and cream—the latter in the proportion of one eighth or one quarter.

LUNATIC ASYLUMS IN THEIR RELATIONS TO THE COMMUNITY.—Dr. R. N. CHASE, of the Norristown Asylum, in a paper on this subject, spoke forcibly of the improbability of truth in the sensational charges often made against asylum officials of retaining sane persons in custody. Individual cases were referred to in which the charges had proved utterly unfounded. There was, however, one great disadvantage consequent upon the cure of the insane: restored to reason and to marital relations, a person that had been insane was prone to hand the taint down to offspring that would have had no existence had this restoration not been effected.

In the discussion on this paper, several gentlemen testified that the American Association for the Protection of the Insane had no disposition to attach undue weight to such charges as Dr. Chase had spoken of, and one gentleman spoke from personal knowledge of the groundlessness of the charges in the Dixmont case. Others thought that, for reasons not connected with any discreditable motive on the part of asylum authorities, patients were detained in many instances long after a period when they would be better off at their homes. One speaker called attention to the frequency with which alcoholic poisoning was mistaken for incipient insanity, the individual being consequently sent to an asylum, where his name went to swell the figures of lunacy statistics, thus helping to lend prominence to the alleged increase of insanity.

SIMPLE METHODS OF TREATING CLUB-FOOT.—Dr. DE FOREST WILLARD, of Philadelphia, read a paper in which he dwelt particularly on the necessity and the efficiency of simple measures employed immediately after birth in cases of congenital club-foot. Manual manipulation, frequently repeated, was especially recommended. This should be attended to by the nurse. The use of adhesive plaster, various adaptable splint materials, immovable bandages, and elastic traction, would often result in doing away with the need of operative interference at a later period; at all events, the aggravation of the deformity would be prevented to a great degree, pending the proper time for such interference.

THE PRESIDENT'S ADDRESS.—At the evening session, the doors having been thrown open to the public, the President,

Dr. WILLIAM VARIAN, of Titusville, gave the annual address. After sketching the organization and early career of the society, and drawing attention to its services in promoting legislation relative to sanitary measures, he spoke of one work it had yet to do in that direction—to secure the establishment of a State board of health. He regarded the disposal of the dead by cremation as in every way the most appropriate and hygienic method. The subject of inebriate asylums was then touched upon, stress being laid on the insufficient length of time during which the patients were often kept under watch. State supervision was urged in the matter of the production of vaccine virus. The speaker's own preference was for humanized vaccine, after several years' trial of animal virus. He recommended that State medicine and hygiene should form a part of the regular curriculum in medical colleges. He then called upon the society to repeat its former expressions of disapproval of the action of the Medical Society of the State of New York in reaffirming its renunciation of the code of ethics of the American Medical Association, denouncing that action as unjustifiable and revolutionary.

THE NOMINATING COMMITTEE.—At the second day's session, after a prayer by the Rev. Mr. KIEFFER, of the Reformed Church, the announcement of the members of the Nominating Committee from the different counties was made, as follows: Adams, A. S. Knobl; Alleghany, T. G. Gelleser; Armstrong, K. L. McCurdy; Blair, W. R. Finley; Bradford, E. P. Allen; Buck, Joseph Foulke; Cambria, M. J. Donnelly; Centre, Philip S. Fisher; Chester, Edward Jackson; Clearfield, S. C. Stewart; Columbia, L. B. Kline; Crawford, G. O. Moody; Cumberland, R. L. Sibbett; Dauphin, Hugh Hamilton; Delaware, I. N. Curlin; Erie, J. L. Stewart; Fayette, Ellis Phillips; Franklin, John Montgomery; Huntingdon, A. B. Brumbore; Indiana, U. B. Easley; Jefferson, U. B. Gibson; Lancaster, J. A. E. Reed; Lackawanna, J. U. Gibbs; Luzerne, Louis Taylor; Lycoming, John W. Young; Mifflin, A. Rothrock; Montour, S. S. Schultz; Northampton, C. McIntyre, Jr.; Philadelphia, W. G. Porter; Schuylkill, J. S. Callan; Snyder, J. F. Kalmwell; Venango, S. Gustine Snowden; Warren, F. A. Slingart; Westmoreland, J. A. Fulton; York, U. S. Roland.

THE ADDRESS IN SURGERY.—This was read by Dr. A. CRAIG, of Columbia. The treatment of injuries, especially of fractures, formed a prominent topic of remark.

THE TREATMENT OF SCARLET FEVER.—Dr. E. O. BARDWELL, of Emporium, read a paper in which he stated his belief in the inadequacy of quinine as an antipyretic, and his preference for packing the patient.

DEFORMITY AFTER POTT'S FRACTURE.—Dr. E. A. WOOD, of Pittsburg, called attention to the mechanism by which a spreading of the malleoli apart, with consequent eversion of the foot simulating valgus, was sometimes witnessed in cases of injury at the ankle in which, with more or less fracturing of the lower end of the tibia or of the fibula, the prominent feature at the time was the outward dislocation of the foot. When repair appeared to be complete, the contour of the ankle might at first be all that could be desired, but walking was apt to induce the deformity alluded to, by forcing the astragalus against the outer malleolus.

TYPHILITIS AND PERITYPHILITIS.—Dr. WILLIAM PEPPER, of Philadelphia, read an important paper on this subject, dealing with it from a clinical standpoint, and insisting particularly upon careful treatment during convalescence.

THE THOROUGH REMOVAL OF CANCER OF THE BREAST.—Dr. SAMUEL W. GROSS, of Philadelphia, read a paper in which he recommended that the whole breast should be removed, together with its integument, the fascia covering the pectoral muscle, and any enlarged glands that might be found in the ax-

illa, even in cases where the growth was very small, and where the skin seemed quite sound. To this radical method of removal the speaker attributed his success in preventing a recurrence of the disease. Several patients were shown on whom he had done the operation, and the healthy state of the cicatrices was demonstrated.

THE TREATMENT OF PURULENT PLEURAL EFFUSIONS.—Dr. JAMES C. WILSON, of Philadelphia, referred to the joints in the diagnosis of empyema, and expressed his conviction that repeated aspiration, while it was often successful with children, could not be depended upon in the case of an adult. It was necessary to establish a fistulous opening; a spontaneous opening, either outwardly or into a bronchial tube, would not answer. It was best, on account of the dyspnoea, not to administer an anæsthetic at the time of the operation, but to trust to local anæsthesia by freezing the skin.

THE MEDICAL SERVICE OF LUNATIC HOSPITALS.—In a well-considered paper on this subject, Dr. CHARLES K. MILLS, of Philadelphia, urged the necessity of a more ample provision of facilities of a purely medical sort in the management of asylums, such as an increase in the force of the resident staff, the establishment of boards of consulting alienists, and the appointment of a pathologist at each institution.

VIVISECTION.—A communication was read from the American Anti-vivisection Society, asking attention to the matter of vivisection. It was referred to a committee, to report next year.

PROVISION FOR ANATOMICAL STUDY.—A resolution was adopted urging the Legislature of the State to pass the amended anatomy bill, now before the House of Representatives.

THE ARMY MEDICAL MUSEUM AND LIBRARY.—On motion of Dr. SAMUEL D. GROSS, of Philadelphia, a resolution was passed asking Congress to provide a suitable fireproof building in Washington for the Army Medical Museum and the Library of the Surgeon-General's Office.

OFFICERS FOR THE ENSUING YEAR.—The Nominating Committee reported the following list of officers for the coming year: President, Dr. Henry H. Smith, of Philadelphia; Vice-Presidents, Drs. Ellis Phillips, of New Haven; H. B. Vannalzal, of Clearfield; J. M. Kerr, of York; S. S. Shultz, of Danville; Permanent Secretary, Dr. William B. Atkinson, of Philadelphia; Recording Secretary, Dr. Morris S. French, of Philadelphia; Corresponding Secretary, Dr. John G. Lee, of Philadelphia; Treasurer, Dr. Benjamin Lee, of Philadelphia; additional members of the Committee on Publication, Drs. Hugh Hamilton, of Harrisburg; James Tyson and C. S. Turnbull, of Philadelphia; Judicial Council, Drs. A. Rothrock, of McVeytown; G. O. Moody, of Titusville; William Pepper, of Philadelphia.

AN ADDRESS IN OPHTHALMOLOGY.—At the morning session of the third day, Dr. EDWARD J. JACKSON, of West Chester, introduced the following:

Resolved, That at each annual meeting the president appoint one member to deliver, at the next yearly meeting, an address on ophthalmology and its relation to general medicine.

Dr. W. S. LITTLE, of Philadelphia, moved to amend by adding otology and laryngology. After considerable discussion, the regular order of the day was demanded. The demand having been sustained, Dr. Jackson's resolution was laid over for the time being, but was subsequently passed.

THE ADDRESS IN PSYCHIATRY.—Dr. JOHN CURWEN, of Warren, delivered the address in psychological medicine. It was an interesting paper, dealing largely with the etiology of insanity and of nervous diseases in general, their increasing prevalence and intractability, and the hygienic measures best suited to diminish the frequency of their transmission from generation to generation.

The address was followed by a number of voluntary papers. For lack of space, we can only mention their titles, as follows: "The Diagnosis, Prognosis, and Treatment of Mitral Constriction," by Dr. J. T. Eskridge, of Philadelphia; "Lithæmia," by Dr. James B. Walker, of Philadelphia; and "Clinical Notes on the Use of *Convallaria Maialis*," by Dr. Edward T. Bruen, of Philadelphia.

A PROPOSED AMENDMENT TO THE BY-LAWS.—On behalf of the Philadelphia County Medical Society, Dr. HENRY LEFFMAN, of Philadelphia, moved an amendment to the by-laws, the substance of which was that in the future no paper should be read before the society unless it had previously been read before a county society, and by the latter referred to the State society. Under the rules, the amendment was laid over for one year.

CONSULTATIONS WITH HOMŒOPATHISTS.—At the afternoon session a communication from the West Philadelphia County Medical Society was read, embodying a resolution adopted by that society urging that the dignity of the profession should be maintained by refusing to consult with the adherents of an exclusive dogma. The communication was ordered to be entered on the minutes.

Dr. B. LEE, of Philadelphia, presented a report from the Committee on the Codification of the Lunacy Laws. The following voluntary papers were read: "The Hair, its Use and its Care," by Dr. John V. Shoemaker, of Philadelphia [for an abstract of which, see p. 537]; "The Possibility of Abnormal Ocular Conditions impairing the Functions of the Uterus through the Sympathetic System," by Dr. W. S. Little, of Philadelphia; and "The Hygienic Management of Consumption," by Dr. J. M. Anders, of Philadelphia.

THE ADDRESSES FOR 1884.—The president announced the following appointments: Address in medicine, Dr. W. H. Daly, of Pittsburg; address in surgery, Dr. John B. Roberts, of Philadelphia; address in obstetrics, Dr. Jacob Price, of West Chester; address in hygiene and State medicine, Dr. John G. Lee, of Philadelphia; address in psychological medicine, Dr. Alice Bennett, of the Norristown Asylum.

DELEGATES TO OTHER SOCIETIES.—The appointment of the following delegates was announced: To the *American Medical Association*—S. R. Rutledge, of Blairsville; J. L. Stewart, of Erie; R. A. Campbell, of Lewistown; George F. Horton, of Terrytown; W. S. Roland, of York; J. W. C. O'Neal, of Gettysburg; R. Rothrock, of Middleburg; R. L. McCurdy, of Freeport; W. T. Bishop, of Harrisburg; David Engleman, of Easton; E. A. Wood, T. J. Gallagher, and John Semple, of Pittsburg; J. Willis Houston, of Oxford; Thomas Lyon, of Williamsport; J. F. Shepler, of Dunbar; Oscar H. Allis and H. St. Clair Ash, of Philadelphia; H. W. McReynolds, of Bloomsburg; J. W. Tweedle, of Weatherby; J. C. Sheridan, of Cambria; C. Lenker, of Schuylkill; R. H. Chase, of Norristown; Harvey Kratz, of Hilltown. To the *Delaware State Medical Society*—Henry Price, of Kennett Square; W. G. Porter, J. C. Wilson, L. K. Baldwin, and J. A. McFerran, of Philadelphia. To the *Massachusetts State Medical Society*—E. P. Allen, of Athens; P. B. Breining, of Bethlehem; Alice Bennett, of Norristown; G. K. Halberstat, of Pottsville. To the *Medical and Chirurgical Faculty of Maryland*—Hugh Hamilton, of Harrisburg; C. F. Spanler, of York; Edward Jackson, of West Chester; E. T. Bruen and F. P. Henry, of Philadelphia; and R. S. Seiss, of Littlestown. To the *Ohio State Medical Society*—C. B. Kibler, of Coney; J. G. Cunningham, of Kittanning; Charles T. Hunter, of Philadelphia. To the *New Jersey State Medical Society*—Thomas D. Dunn, of West Chester; H. H. Whitcomb and E. M. Corson, of Norristown; Henry Leffman, J. T. Eskridge, and Joseph Hearn, of Philadelphia; and G. D. Nutt, of Williamsport. To the *West Virginia State Medical Society*—

George Stiles, of Conshohocken; W. J. Asdale, of Pittsburg; Charles S. Turnbull, of Philadelphia, and Frank Ehrenfeld, of Indiana.

The meeting then adjourned. The next annual meeting will be held in Philadelphia.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A STATED meeting was held November 25, 1882, Dr. T. GAILLARD THOMAS, President, in the chair.

TENDENCY TO THE DEVELOPMENT OF DIFFERENT VARIETIES OF MALIGNANT DISEASE IN THE SAME PATIENT.—The PRESIDENT related the following case: A woman, forty years of age, was sent to the Woman's Hospital by a physician who had diagnosed ovarian tumor. The tumor was very hard, immovable, was estimated to weigh thirty pounds, and was doubtless a sarcoma of the ovary; yet the patient was feeling well, and had the appearance of perfect health. On inquiry, it was found that she had previously been to see a so-called cancer doctor, who applied a caustic to a tumor on the breast which was now in a sloughing condition; the other breast was hard and retracted, the seat of ordinary scirrhus cancer. A vaginal examination was then made, and the entire cervix uteri was found to have been destroyed by carcinoma. The patient had menstruated regularly, and, as said before, had the appearance of perfect health.

LAPARO-ELYTROTOMY.—Dr. G. G. WHEELOCK stated that he had recently performed this operation on the cadaver of a primipara who died undelivered at term. When he saw the patient she was in profound coma, had had many convulsions, and was evidently dying with a pulse of 180 and a temperature of 106°. The friends stated that she was at term; vaginal examination revealed the os entirely undilated, and no labor pains had been observed. All attempts at producing dilatation were unsuccessful beyond a very limited extent, and brought on no pains. The patient died within half an hour, and, as no fetal motions had been made out and the fetal heart could nowhere be heard, their was no indication for the operation of Cæsarean section. On the next day the operation of laparo-elytrotomy was performed. Before making the incision the os was forcibly dilated, but it required about fifteen minutes to accomplish it, and the cervix was somewhat lacerated in the process. An incision four and a half inches in length was made in a line from the right anterior superior spinous process of the ilium toward the symphysis pubis, though not extending to the median line. The superficial epigastric artery was divided. The deep artery was seen, but not divided. After working with the fingers down to the vagina, a sound was passed from without through the vagina and pressed upward close to the cervix, forming a projection on which the incision was made. After the vaginal wound had been considerably enlarged by stretching with the fingers, a blunt hook was passed through it and engaged in the cervix, and traction made so as to tilt the organ laterally while the fundus was pressed over in the opposite direction by an assistant. As the patient was a primipara, and the abdominal walls were very tense, and the cadaver very rigid, being nearly frozen, great difficulty was found in accomplishing this part of the operation. Finally, however, the fingers were introduced and version was performed, and the child extracted. An examination of the parts after the operation showed that the ureter remained uninjured below the incision, and the ovarian and uterine vessels also had escaped injury; the cervix was considerably lacerated. Notwithstanding these difficulties, Dr. Wheelock believed that, had the child been living, its life could have been saved, that the difficulties encountered were greater in the post-mortem condition than would ordinarily exist ante-mortem, and that in most cases calling for

the operation no such unyielding condition of the os would ordinarily be met with. The woman had died in uræmic coma, and the child had already been dead some hours before that time.

In reply to a question, the PRESIDENT said he had performed laparo-elytrotomy in two cases, in both cases extracting a living child. In one the woman had been in labor a long time, and was in *articulo mortis* when the operation was performed.

Dr. W. M. POLK thought the extent of the abdominal incision, as usually recommended in these cases, was too limited. There could be no impropriety in carrying it at least an inch above the anterior superior spinous process of the ilium. If the epigastric arteries were divided, no particular harm would be done; circulation would be carried on by anastomosis. Thus, an incision at least five inches in length would be made, through which the child could easily be extracted. He reiterated his belief, as expressed on former occasions, that the operation involved little or no danger to the ureter, to the blood-vessels, nor to the tissues, and that in many cases it was certainly destined to supersede the Cæsarean section.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A STATED meeting was held Thursday, January 1, 1883, Dr. T. M. DRYSDALE, 1st Vice-President, in the chair.

DEATH FROM EMBOLISM.—Dr. WILLIAM GOODELL reported the death of the patient from whom he had removed a uterine myofibroma (case reported by Dr. Baer, in the discussion on Dr. Drysdale's paper, at the meeting of December 7, 1882). The patient had progressed favorably, but some weeks after the operation, while straining at stool, she had evidently loosened a portion of clot on the proximal side of one of the venous ligatures. It passed into the pulmonary circulation and quickly caused death.

WHAT IS THE PROPER MANAGEMENT OF THE BOWELS AFTER PERINEORRHAPHY?—Dr. GOODELL had recently operated, for the relief of lacerated perineum, upon an insane woman who had been sent to him for that purpose from an asylum. Her insanity commenced after labor, and was probably due to a complete laceration of the perineum extending two inches up the rectum. It had always been his habit to prevent any action of the bowels during the first week after the operation. This patient, soon after coming out from the influence of the anæsthetic, tore off the bandage from her knees, removed the catheter, and, by severe straining efforts, secured a movement from the bowels. As she could not be controlled, laxatives were given to secure liquid stools and avoid straining. The patient walked freely about the ward from the day of operation. The doctor expected the operation to be a failure under such circumstances; but to his surprise, on removing the sutures, he found that in the rectal portion and the important part of the perineum union had taken place.

His attention had been called by this case to the question of the advisability of keeping the bowels constipated after this operation. He intended to try the effect of laxatives in future cases.

Dr. R. P. HARRIS reported the case of a woman who, after the operation of perineorrhaphy, would strain, and her efforts at defecation opened the wound to nearly its original extent. In a second operation on the same patient the bowels were kept free and union was perfect.

Dr. E. E. MONTGOMERY, after operating for lacerated perineum, did not use a catheter, but allowed the patient to pass her water, as he did not consider healthy urine disadvantageous for a wound. He had been in the habit of using compound licorice-powder to keep the stools liquid. He had had good success

in both primary and secondary operations upon the perineum where the rectum was involved.

The following members were then elected officers for 1883: President, Dr. Richard A. Cleemann; Vice-Presidents, Drs. B. F. Baer and W. T. Taylor; Secretary, Dr. W. H. H. Githens; Treasurer, Dr. Alfred Whelen; Librarian and Curator, Dr. E. E. Montgomery; Publication Committee, Drs. John H. Packard, Elliott Richardson, James V. Ingham, B. F. Baer; Councillors, Drs. R. P. Harris, L. D. Harlow, Wm. Goodell, T. M. Drysdale; Library Committee, Drs. Horace Williams, D. M. Cheston; Committee on Proceedings, Drs. A. H. Smith, E. E. Montgomery.

W. H. H. GITHENS, M.D., *Secretary*.

Reports on the Progress of Medicine.

QUARTERLY REPORT ON ORTHOPÆDIC SURGERY AND DISEASES OF THE JOINTS.

No. XII.

By CHARLES T. POORE, M.D.,

SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN.

THREE CASES OF BONE DISEASE IN CHILDHOOD LEADING TO DEFORMITY.—Mr. Barwell exhibited at the London Pathological Society ("Brit. Med. Jour.," Feb. 24, 1883) three patients. The first was a boy eight years of age. One tibia was thickened, was an inch longer than the other, and bent forward; this was due, he thought, to hyperplasia of the bone, and was not rachitic. The second was a girl, four and a half years of age, who was extremely rickety. Both tibiae were much bent forward, and were not of equal length; this condition Mr. Barwell also attributed to hyperplasia. Both cases, he contended, showed that the deformity in rickets was not due merely to the weight of the body acting on softened bones, but was produced by a hyperplastic malady which affected by preference certain parts of particular bones. His third patient was a man twenty-two years old. He was born healthy and well formed, but at five years of age he suffered from a fever, after which his bones became soft and bent. He presented double genu valgum, curving of the tibia, unlike that seen in rickets, and such great curving of the left radius that the distance, in a straight line, from the head of the bone to the styloid process, was only three fourths of the length of the bone. This case, he thought, was not a case of rickets, but an instance of a disease, inflammatory in its nature, for which there was as yet no name.

CURVATURE OF THE FEMUR.—Mr. Bowlby ("Brit. Med. Jour.," Feb. 24, 1883) exhibited two femora. One was bowed forward, the result of inflammation following on long-continued suppuration produced by an injury; the deformity had appeared early in life. The bone was uniformly curved, and its surface roughened by irregular subperiosteal deposit; the compact tissue of the shaft was thin, and immediately above the condyles was a quantity of soft, mortar-like material; the whole medullary cavity was also occupied by a similar substance. In the second case the curvature of the femur had been gradually produced during the last ten years of the patient's life, and had rendered the affected limb two and a half inches shorter than the other. The patient was a cabman, aged sixty-four. The bone was bent outward and forward in one uniform curve; the shaft was six and a quarter inches in circumference (two and a half inches greater than normal), and rough on the surface. Some parts of the neck and head of the bone presented changes like those seen in rheumatoid arthritis.

DEFORMITY OF THE THIGH GRADUALLY DEVELOPED AFTER AN

INJURY.—Mr. Thomas Smith ("Brit. Med. Jour.," Feb. 24, 1883) gives the history of a girl, seventeen years of age, who, eighteen months earlier, had a fall which seemed to have caused some considerable injury, since, though she was told that her thigh was not broken, she had been kept in bed for two months. Since that time the shape and position of the femur had gradually altered, resulting, finally, in extreme deformity, the bone being bent outward at about the junction of the upper and middle thirds. Mr. Smith thought there might be a little motion at the seat of deformity, but was doubtful. He advocated an attempt at osteoclasis, and, if that failed, osteotomy.

CARIES OF THE SPINE IN TAILORESSES.—CASE I.—Mr. John Hopkins reports ("Lancet," March 31, 1883) three cases of disease of the vertebrae occurring in tailoresses. The first patient was sixty-nine years of age; she suddenly lost the use of both lower limbs; previously she had complained only of a feeling of dejection and indisposition to work. There were increased reflex movements. The seventh dorsal vertebra was slightly prominent, pains occasionally shot down the front of the thighs, the bladder was distended, and the bowels were confined. The prominence of the vertebra became more marked. The patient died five weeks after the onset of the paralysis. On post-mortem examination, the bodies of the seventh and eighth dorsal vertebrae were found carious. The spinal cord was compressed by abscesses pressing backward.

CASE II.—A tailoress, forty-four years of age, who, when a child, was delicate, came under observation with a large abscess over the left thoracic parietes. For the past five years she had been feeling ill, but had no pain: Four months ago a swelling appeared on the left side; this was opened, and a piece of dead bone came away. One month later the patient began to experience pain in the right shoulder; later, pain and stiffness of the neck; then retention of urine and paralysis of the lower extremities; and finally she died from dyspnea. On post-mortem examination, the outer half of the right transverse process of the first dorsal vertebra was found broken off and reunited by firm fibrous bands, both to the part from which it had been broken and to the posterior transverse process of the dislocated seventh cervical. Caries had destroyed nearly the whole of the body of the first dorsal and the under-surface of the seventh cervical vertebra. An abscess had passed between the bodies and the posterior common ligament, thus compressing the cord.

CASE III.—A tailoress, aged thirty-four, who when a child had had an abscess and necrosis. When she came under observation, she had lost power over the lower limbs, and gave a history of caries of the vertebra, seventh, eighth, and ninth dorsal. She died from exhaustion. No post-mortem was held.

NECROSIS OF THE PATELLA LEADING TO DISEASE OF THE KNEE JOINT.—In the "Lancet," April 7, 1883, Mr. G. A. Wright reports two cases of this quite rare disease. The first was in a boy, eight years of age, who, six months before coming under observation, fell and injured his knee; one month later the joint became swollen, red, and tender. Under treatment he almost recovered, when the knee was again injured. The inflammation was lighted up, and an abscess appeared and discharged. The right knee was considerably swollen, but the swelling was almost entirely limited to the tissues around the joint, there being but little effusion apparent within it. There were three sinuses on the front and side of the knee freely communicating. These were freely laid open. After the joint became more swollen and tender, free incisions were made into it. The synovial membrane was swollen, but the cartilage seemed healthy, except one circular spot, about half an inch in diameter, in the center of the patella; here a perforation existed which ran completely through the bone and communicated freely with the openings on the front of the knee. The wounds were treated antisepti-

cally; some burrowing of pus took place, and, after some months, he was discharged with an immovable apparatus and was lost sight of.

The second case was in a boy, seven years of age, who, ten weeks before being seen, received a blow upon the left knee, and the joint became painful and weak; there does not appear to have been any acute inflammation, and it did not discharge until five days before he came to the hospital. The left knee was found to be swollen and fluctuating, the swelling mapping out the synovial sac. The skin was somewhat red and the veins turgid, but there was little tenderness. A sinus was seen over the front of the ligamentum patellæ. On exploring the sinus, it was found to lead to the upper surface of the patella. On laying the track open, a sequestrum of the size of a damson-stone was found loose in the center of the bone, and, on removing it, a perforation into the joint was seen.

NON-UNION OF THE TIBIA AFTER OSTEOCLASIS.—In the "Medical News," April 14, 1883, Dr. Fifield reports a case of non-union after osteoclasis. It occurred in a girl, five years of age, who was admitted into the Children's Hospital, Boston, with bowing of the arms and legs. On August 30, 1880, the left tibia, and in October the right leg and arm, were fractured with the osteoclast. The limbs were put up in a stiff bandage, and united in a good position in a few weeks, except the left leg, which did not unite firmly. There was here considerable projection forward of the tibia at the seat of fracture. On March 24, 1881, it was again fractured, but it failed to unite. In June, 1882, there was considerable bowing forward at the seat of the former operation, and considerable mobility. What union there was was broken down, and the limb again placed in a plaster bandage. On October 20, 1882, the limb was in the same condition; a cuneiform osteotomy was performed, and the ends of the bone wired together, after which firm union took place. The bone at the seat of operation was found chronic, inflamed, thickened (sclerosed?).

TRANSPATELLAR EXCISION OF THE KNEE.—At a meeting of the London Clinical Society ("Lancet," June 20, 1883), Mr. Golding-Bird read a paper on the above subject. The operation was performed on a boy thirteen years of age. There was a year's history of articular osteitis of the right knee, with pulpy disease. In excising, a transverse incision was made across the middle of the patella, which was then sawn in two. The two fragments, with the soft parts, being turned up and down, the excision was completed in the usual way. Some pulpy thickening was removed from the lower side of the patella, and, when the limb was straightened, two carbolized-silk sutures were passed through its substance, and its two fragments thus united. Primary union was obtained. For four months the patient walked about with a stiff bandage at the knee, and with crutches. He had now a movable patella, and half an inch shortening.

The advantages claimed were that the surgeon could manipulate the joint better than when, with the idea of retaining the patella, the lateral incisions were employed; that, by keeping the normal attachments of the patella, the quadriceps opposed the ham-strings, so that the necessity was obviated of employing a stiff bandage for a year, to prevent posterior displacement of the leg; the rectus femoris had its full play upon the trunk in preserving equilibrium.

[Lack of space compels us to omit the publication of the bibliographical list appended to Dr. Poore's Report.]

THE TRANSACTIONS OF THE NEW YORK ACADEMY OF MEDICINE.—We are asked to state that volume iii. of the new series is now ready, and that Fellows may obtain it at cost price on application to the assistant librarian, Mr. John S. Browne, at the Academy, No. 12 West Thirty-first Street.

Miscellany.

THE NEW CODE IN HORNELLSVILLE.—Under date of May 9th, Dr. C. G. Hubbard, Secretary of the Hornellsville Academy of Medicine, writes as follows: "At the regular monthly meeting of the Hornellsville Academy of Medicine, held on Monday evening, May 7th, its constitution was amended by a unanimous vote in favor of the new code. Notice of the intended change was given at the previous meeting, and of the forty members no one was present to oppose the new code. The sentiment of the fraternity in this region is all one way."

THE AMERICAN LARYNGOLOGICAL ASSOCIATION.—At the fifth annual meeting, which, as we have before announced, will be held at the Academy of Medicine on the 21st, 22d, and 23d inst., the following papers are expected to be read: *Monday Morning*.—"New Facts in Laryngology," by George M. Loefferts, M. D., New York; "A Common Form of Vocal Disability resulting from Pathological Processes: the Phenomena used to demonstrate the Futility of One System of Voice Training," by S. W. Langue, M. D., Boston. *Monday Afternoon*.—"The Destruction of Nasal Polypi by Chromic Acid," by Frank Donaldson, M. D., Baltimore; "Chorea Laryngis," by Frederick I. Knight, M. D., Boston; "The Treatment of Laryngeal Phthisis," by W. C. Jarvis, M. D., New York; "Paresis of the Constrictor Muscles of the Pharynx, simulating Spasmodic Structure of the Esophagus, with Report of Cases," by Frank H. Bosworth, M. D., New York. *Tuesday Morning*.—"On Photographing the Larynx," by Thomas R. French, M. D., Brooklyn; "Congenital Tumors of the Larynx, with a Report of Cases," by H. A. Johnson, M. D., Chicago; "Laryngeal Paralysis from Aneurysm," by William Porter, M. D., St. Louis. *Tuesday Afternoon*.—"Reflex Phenomena due to Nasal Disease," by Louis Elsborg, M. D., New York; "Smell, Hygienically and Medico-Legally considered," by Clinton Wagner, M. D., New York; "Asymmetry of the Nasal Chambers," by Harrison Allen, M. D., Philadelphia; "On the Results of the Treatment of Naso-Pharyngeal Polypi, with Demonstration of Successful Cases," by Rufus P. Lincoln, M. D., New York. *Wednesday Morning*.—"A case of Thyrotomy for Morbid Growth; with Subsequent Development of Epithelioma in the Cutaneous Cicatrix, but without Involvement of the Interior of the Larynx," by J. Solis Cohen, M. D., Philadelphia; "Experimental Researches on the Tension of the Vocal Bands," by F. H. Hooper, M. D., Boston; "Aural Complications of Inflammatory Conditions of the Nose and Throat," by Beverley Robinson, M. D., New York; "The Lacunæ Tonsillares," by D. Bryson Delavan, M. D., New York. *Wednesday Afternoon*.—"The Value of Post-Laryngeal Papillomata as a Means of Diagnosis in Tubercular Disease," by George W. Major, M. D., Montreal, Canada; "A Case of Enormous Tumor removed from the Glosso-Epiglottic Sinus, with Remarks," by E. C. Morgan, M. D., Washington; "A Case of Sudden Death occurring after Tracheotomy, with Remarks," by Morris J. Asch, M. D., New York; "On Adhesion of the Velum to the Walls of the Pharynx," by Andrew H. Smith, M. D., New York.

The annual dinner will take place at Delmonico's Monday evening at 7 o'clock. On Tuesday evening the president, Dr. Loefferts, gives a theatre party, to be followed by a supper at Delmonico's.

OHIO STATE MEDICAL SOCIETY.—The first session of the thirty-eighth annual meeting of the society will be held at half-past nine o'clock a.m. on Tuesday, June 5th, at the "Tabernacle" on Ontario street, Cleveland. The Committee of Arrangements of the American Medical Association having formally extended to the society, through its Committee of Arrangements, an invitation to arrange for a single session of the State society, at which only necessary business shall be transacted, and then to adjourn and to have the members become members by invitation of the American Medical Association, the Committee of Arrangements of the State society will, in their report, recommend an acceptance of the invitation.

THE PLAGUE IN PERSIA.—The International Sanitary Committee at Constantinople, says the "Lancet," upon hearing that the plague had again broken out in Persia, close to the Turkish frontier, dispatched a

physician to the district, and they received from him last week a telegram to the effect that "the epidemic which prevails in the Persian villages of Zeilan and Bekir Bey, in the district of Djivanro, is the bubonic plague. All the persons who have been attacked have had bubos, and there have been one hundred and seventy deaths up to this date." The district of Djivanro is situated to the southeast of the Turkish province of Suleimaneh, to the south of Selma, near the route to Tauris. The villages in which the plague has declared itself are about equidistant from Suleimaneh and Khaneqadeh, through which latter place pass the caravans conveying the dead bodies of the Persians for burial in the holy places of Bagdad and Irak Arabi. The district thus afflicted is more than ninety miles south of Lake Urmiah, where the plague made its appearance last year, and this is the first time that the dread malady has been known to break out so far south. The conclusion to be drawn from this is that the plague in Persia has a marked tendency to spread toward South Kurdistan, and unless this tendency is checked it will eventually find its way into the Irak, through the Turkish districts, or through Kirmanchah. It is said, however, that the Kurds are taking energetic measures to prevent the epidemic from reaching them, and that a strict quarantine has been established upon the Turkish frontier.

FIBROMA OF THE ROUND LIGAMENT.—Professor Ludwig Kleinwächter describes, in a recent number of the "Zeitschrift für Geburtshilfe und Gynäkologie," a case of fibroma of the round ligament, which is interesting on account of the extreme rarity of that condition. The only case which Professor Kleinwächter has been able to find is described by Winckel, and in it neither of the tumors, of which there was one on each round ligament, exceeded a bean in size. Dr. Kleinwächter's case was that of a multipara aged forty-four. The tumor reached to two fingers' breadths above the umbilicus, it caused slight pain, and was said to increase in size before and during each menstruation. The tumor was situated more to the right than to the left of the middle line, and when it was pushed upward pain was complained of in the region of the right Poupert's ligament. The uterus was pushed to the right of and behind the tumor, which filled the pelvic brim. The tumor was removed, the operation being long and difficult, owing to the number of adhesions present. The clamp was applied to the pedicle, and two drainage tubes inserted. The patient died from peritonitis on the third day. On autopsy, both ovaries and tubes were found healthy, and the pedicle of the tumor was situated on the left round ligament, about an inch from its origin. The uterus was enlarged, but the nature of the enlargement is not stated. The tumor was solid, fibrous in structure, and weighed about three pounds and a half. Looking at the rarity of this disease of the round ligament, the numerous adhesions present, and the uterine enlargement, it might be suggested, and it is to be regretted that Professor Kleinwächter does not discuss the point, that the tumor was originally a uterine fibroid which had become united by adhesions to the round ligament, and subsequently severed from its old attachment.—*Med. Times and Gazette.*

THE CHARITY ORGANIZATION SOCIETY.—At the recent monthly meeting Dr. S. O. Van der Poel was elected president.

THE ASTLEY COOPER PRIZE.—The next triennial prize of three hundred pounds, under the will of the late Sir Astley P. Cooper, Bart., will be awarded to the author of the best essay or treatise on "Diseases and injuries of the nerves and their surgical treatment, together with the operations performed upon nerve-trunks in the treatment of various diseases, and descriptions of the changes which ensue in other structures as well as in the nerves themselves from these operations."

The condition annexed by the testator is, "That the essays or treatises to be written for such prize shall contain original experiments and observations, which shall not have been previously published; and that each essay or treatise shall, as far as the subject shall admit, be illustrated by preparations and by drawings, which preparations and drawings shall be added to the Museum of Guy's Hospital, and shall, together with the work itself and the sole and exclusive interest therein and the copyright thereof, become henceforth the property of that institution, and shall be relinquished and transferred as such by the successful candidate." It is expressly declared in the will "that no physician or surgeon, or other officer for the time being, of Guy's Hos-

pital or of St. Thomas's Hospital, in the borough of Southwark, nor any person related by blood or affinity to any such physician or surgeon, for the time being, or to any other officer for the time being in either of the said hospitals, shall at any time receive or be entitled to claim the prize." With the exception here referred to, this prize is open for competition to the whole world, but it can not be awarded to any essay that is the joint production of two or more authors.

Essays, either written in the English language, or if in a foreign language, accompanied by an English translation, must be sent to Guy's Hospital on or before January 1, 1886, addressed to the Physicians and Surgeons of Guy's Hospital. Each essay or treatise must be distinguished by a motto, and be accompanied by a sealed envelope containing the name and address of the writer. None of the envelopes will be opened except that which accompanies the successful treatise. The unsuccessful essays or treatises, with the illustrative preparations or drawings, will remain at the Museum of Guy's Hospital until claimed by the respective writers or their agents.

DAMAGE TO THE HARVARD MEDICAL SCHOOL'S NEW BUILDING.—The new building for the Harvard Medical School, a description of which appeared in the "Journal" of April 14th, was damaged by fire last Friday evening, May 11th. On account of the fire-proof walls and ceilings, the fire was confined entirely to the large amphitheatre, which occupies part of two stories, and to one of the hallways. The damage amounts to about \$2,000, and will fall upon the contractors, the building not having yet been accepted by the university authorities. Undoubtedly a searching investigation will be made as to the cause of the fire, but the general belief is that it originated either from spontaneous combustion in some oiled rags used by the finishers, or from a live coal from a plumber's furnace. The building was soon to have been dedicated and opened for inspection to those who had subscribed the funds for its erection. The invitations were all printed, and were in the hands of a committee for distribution. The building, it is hoped, will be opened to the profession in June at the time of the annual meeting of the Massachusetts Medical Society.

AN ORIENTAL FEMALE MEDICAL STUDENT.—A Brahmin lady of high caste is reported to have started for this country, with the purpose of studying medicine at the Woman's Medical College, in Philadelphia.

THE SWIFT MEMORIAL FUND.—The President of the Alumni Association of the College of Physicians and Surgeons, Dr. W. H. Draper, announced at the recent annual meeting of the association that Mr. James T. Swift had given the sum of \$10,000, as a memorial of his brother, the late Dr. Foster Swift, the income to be devoted to the purchase of physiological apparatus for the college.

THE COMMENCEMENT OF THE COLLEGE OF PHYSICIANS AND SURGEONS.—The seventy-sixth annual commencement was held on Tuesday, the 15th inst., at Steinway Hall. The degree of doctor in medicine was conferred by the President, Dr. Alonzo Clark, on one hundred and twenty-five gentlemen. The Cartwright biennial prize of \$500, open to general competition, was awarded to Dr. Walter Mendelson, an alumnus of the college, for an essay on "The Renal Circulation during Fever." The Harsen prizes, for the best reports of the clinical instruction given at the New York Hospital for a term of four months, were awarded as follows: First prize, \$150, to C. H. May, of New York city; second prize, \$75, to Abram Brothers; third prize, \$25, to P. D. St. John, of Iowa. Each of the Harsen prizes is accompanied by a bronze medal and a diploma. The three Faculty prizes, open only to the ten honor men, for the best practical knowledge of medicine and surgery, as determined at the bedside and in work on the cadaver, were awarded as follows: First prize, \$500, to C. H. May, of New York city; second prize, \$300, to J. H. Frankenberg, of New York city; third prize, \$200, to A. F. Brugman, of New York city.

The college confers an appointment on the house staff of Bellevue Hospital on each of the four honor men who pass the best competitive examinations. This year C. H. May ranked first, but, as he had already accepted another hospital appointment, the four in question were given to J. H. Frankenberg, of New York city; A. F. Brugman, of New York city; C. F. Roberts, of New Hampshire; and A. W. Hurd, of Illinois. The names of the ten honor men, in alphabetical order, are:

A. F. Brugman, of New York city; H. P. Cooper, of Georgia; J. H. Frankenberg, of New York city; A. W. Hurd, of Illinois; Richmond Lennox, of New York city; C. H. May, of New York city; J. E. Newcomb, of Connecticut; H. S. Quin, of New York State; C. F. Roberts, of New Hampshire; and F. L. Sevenoak, of New York State.

A RECEPTION AT THE PHILADELPHIA POLYCLINIC.—On the evening of the 11th inst. a number of gentlemen who found themselves in Philadelphia, on their return from the meeting of the State Medical Society, were tendered an informal reception by the faculty of the Philadelphia Polyclinic and College for Graduates in Medicine.

THE PHILADELPHIA HOSPITAL FOR SKIN DISEASES.—On Friday evening of last week Dr. John V. Shoemaker and his assistants at the hospital received a visit from a number of physicians on their way home from the meeting at Norristown. The resources of the establishment, and especially the new bathing facilities, are said to have been very much admired.

THE PHILADELPHIA WATER SUPPLY.—Steps have recently been taken to diminish the proportion of sewage in the water of the Schuylkill River by building an intercepting sewer from Fairmount Dam to Manayunk, provision having been made for a loan of \$500,000 for that purpose.

SIR SPENCER WELLS.—Mr. T. Spencer Wells, of London, whose name is so closely connected with the establishment of ovariotomy as an accepted operation, has been made a baronet.

DEATH OF SURGEON-GENERAL HOLLOWAY, OF ENGLAND.—Surgeon-General James Lewis Holloway, C. B., Army Medical Department, died at Netley, April 19th, at the age of fifty-seven. At the time of his death Dr. Holloway was the chief medical officer of the Royal Victoria Hospital at Netley, where he was esteemed one of the most capable of administrative officers. His death was the result of a short but exceedingly painful illness.

ARMY INTELLIGENCE.—Official List of Changes of Stations and Duties of Officers of the Medical Department, United States Army, from May 5, 1883, to May 12, 1883.—**BARTHOLOMEW, JOHN H.**, Captain and Assistant Surgeon. The extension of leave of absence granted April 3, 1883, further extended four months. Par. 8, S. O. 105, A. G. O., May 7, 1883. — **BILLINGS, JOHN S.**, Major and Surgeon. By direction of the Secretary of War, to represent the Medical Department of the army at the annual meeting of the American Medical Association to be held at Cleveland, Ohio, June 5, 1883. Par. 10, S. O. 105, A. G. O., May 7, 1883. — **FORWOOD, WILLIAM H.**, Major and Surgeon. By direction of the Secretary of War, to represent the Medical Department of the army at the annual meeting of the American Medical Association to be held at Cleveland, Ohio, June 5, 1883. Par. 10, S. O. 105, A. G. O., May 7, 1883. — **SMITH, JOSEPH R.**, Major and Surgeon. By direction of the Secretary of War, to represent the Medical Department of the army at the annual meeting of the American Medical Association to be held at Cleveland, Ohio, June 5, 1883. Par. 10, S. O. 105, A. G. O., May 7, 1883.

NAVAL INTELLIGENCE.—List of Changes in the Medical Corps of the Navy during the week ending May 12, 1883.—Surgeon F. M. Dearborne, granted six months sick leave. — Passed Assistant Surgeon S. A. Brown, leave extended six months.

SOCIETY MEETINGS FOR THE COMING WEEK.—**Monday, May 21st:** American Laryngological Association (New York); Medico-Chirurgical Society of German Physicians. **Tuesday, May 22d:** American Laryngological Association (second day); Jersey City Pathological Society; New York Academy of Medicine (Council); New York Dermatological Society (private); New York Surgical Society. **Wednesday, May 23d:** American Laryngological Association (third day); Medical Society of the County of New York (Comitia Minora); New York Pathological Society. **Thursday, May 24th:** New York Academy of Medicine (Section in Obstetrics). **Friday, May 25th:** New York Society of German Physicians (private); New York Clinical Society (private); Yorkville Medical Association (private); **Saturday, May 26th:** New York Medical and Surgical Society (private).

Lectures and Addresses.

A LECTURE ON THE

TREATMENT OF ANGINA PECTORIS.*

By PROFESSOR GERMAIN SÉE,

PHYSICIAN TO THE HÔTEL DIEU; MEMBER OF THE FACULTY OF MEDICINE; MEMBER OF THE ACADEMY OF MEDICINE, PARIS.

GENTLEMEN: Before instituting the treatment of anginal pectoris, it is necessary to bear in mind that it may be only a transitory phase of heart disease, destined ere long to give place to the habitual symptoms of a regular cardiac affection. Angina pectoris is not, then, *per se*, always a cause of alarm, even when the attacks seem to be of a typical character. As it is impossible to predict a temporary duration of the malady, it is the duty of the physician, both during the paroxysm and in the interval, to act as though the return of the paroxysms and their attendant danger were inevitable. Above all, the cause should be sought for.

TREATMENT BASED ON ETIOLOGICAL CONSIDERATIONS.—If angina pectoris be due to a poison, it would seem to be a simple matter to prevent the attacks by suppressing the cause.

As for those anginas which have their origin in the abuse of tobacco, the remedy is obvious enough. It must, however, be borne in mind that angina pectoris from tobacco is a rare thing. Tobacco determines intermittences, arrhythmia, etc., much oftener than the painful affection under consideration, which, when the result of smoking, is due to the slow action of the nicotine poison on the coronary arteries.

Angina of alcoholic origin does not yield to suppression of the cause. It is a sure sign, when spirit-drinkers have attacks of angina pectoris, that arterial lesions already exist—that is to say, endarteritis of the coronary vessels, as well as degenerations or scleroses of the myocardium. It is vain to suppress alcohol in these cases; the evil is done, and is almost always irremediable. Gouty angina, which the Germans regard as the typical form, even identifying angina pectoris with gout, is in reality a cardio-vascular lesion, and resists treatment of the diathesis, just as alcoholic angina persists in spite of the suppression of the cause. Even granting that there is a definite medication for the gouty diathesis, as there is for the arthritic manifestations, it is doubtful if one could succeed by such specific treatment in preventing gout from affecting the vascular system, or endarteritis from appearing; in fact, the so much vaunted alkalies can do little for the joint affections, and still less for gout of the heart, or the constitutional condition.

ANGINA PECTORIS OF ORGANIC ORIGIN.—Thus far the causal treatment has been practically nil, with the single exception of angina from tobacco. The anginas of organic origin are not any more amenable to treatment directed at the cause. What can we do to remedy alterations of the coronary arteries, degenerations of the cardiac muscle, dila-

tation of the cavities, and lesions of the aorta, which in reality oftener cause attacks of angina pectoris than mitral lesions? There is no cure for the thoracic angor that results from these grave lesions.

ETIOLOGICAL TREATMENT OF ANGINA PECTORIS OF HYSTERICAL ORIGIN.—It would seem that such cases might be easily remedied, that—bearing in mind the hysterical nature of the affection—a preventive treatment might easily be instituted. Practically, however, hysterical angina is very rare, and the cases which have been reported as such have generally been found to be simulated attacks, or real convulsive attacks, of common hysteria with painful irradiations; the diagnosis was at fault. These pseudo-anginas might almost certainly be benefited by hydrotherapy. Were I certain that I had to do with a genuine case of angina pectoris from hysteria, I would preserve the patient from cold douches, which might have a fatal result. These neurotic anginas, almost, if not quite as dangerous as those of organic origin, can be little benefited by the antispasmodics—asafoetida, valerian, musk, castor, etc.

RÉSUMÉ.—The ætiological treatment of angina pectoris is unsatisfactory and generally unsuccessful; the best that we can do, then, is to treat the paroxysms, and endeavor to prevent their return.

METHODS OF TREATMENT OF THE PAROXYSMS.—In the presence of a patient who is suffering from an attack of angina pectoris, you are to search promptly for something to calm the pain, relieve the breathing, and regulate the circulation. The principal means are, first:

Hypodermic Injections of Morphine.—Hypodermic morphine claims a foremost place by reason of the rapidity of absorption and of physiological action. A centigramme of hydrochlorate of morphine (about one sixth of a grain) ordinarily suffices to alleviate the pain, which is the principal factor in the paroxysm. I am not afraid to repeat the injection to prevent a return of the angor. I have seen, with one of my hospital colleagues, an old man who was cured of his præcordial distress—the result of excitation of the cardiac nerves by organic disease—by the daily use, for several months, of morphine subcutaneously. With the same physician I treated still more recently an eminent political personage who finally succumbed to an attack contracted, in the chilly weather of March, by riding in an open carriage at nine o'clock in the evening in the Bois de Boulogne. As he died in spite of morphine, it was reported that he died from morphine. Latterly, and since the experiments of Fillehne, fear has been expressed that these subcutaneous injections might occasion dyspnoea, and even that dangerous form known as Cheyne-Stokes respiration. This fear can hardly contraindicate the use of the opiate for pain where the element of dyspnoea is absent; if there be any embarrassment of respiration, it is owing to the pain, and nothing else.

Nitrite of Amyl.—Recommended as far back as 1857 by Guthrie, then by Gamgee, Brunton, Wood, more recently by Pick, Guttman, Schram, Otto, of Germany, thoroughly studied in France in 1873, by Amez-Droz, then by Bourneville, and Dujardin-Beaumez, nitrite of amyl constitutes

* Translated, with Professor Sée's permission, by E. P. Hurd, M. D., Newburyport, Mass.

one of the most active and most useful means in the treatment of angina pectoris.

Physiological Effects.—Experimental physiologists—Fيلهne and Mayerin Germany, Duceau and Franck in France—have very recently been occupied in investigating the effects of this singular toxic agent, whose *modus operandi* they have defined. First of all, the effects of nitrite of amyl on healthy animals and healthy human beings are as follows:

Action on the Blood-Vessels.—Reddening of the skin and internal organs. The first effect of nitrite of amyl, inhaled in the dose of from two to four drops, is reddening of the face and neck, with red spots on the chest and mottling of the abdomen, but no red markings of the lower extremities. The same reddening is seen in the internal cephalic organs, among others the pia mater, whose blood-vessels are markedly dilated, at the same time that the retina and the lungs remain in the normal state.

Dilatation of the Vessels.—The most remarkable phenomenon, then, is dilatation of the blood-vessels, and this is attended with diminution of vascular tension, which may fall to 0.050 millimetre.

Causes of the Vascular Dilatation and Depression.—Either this is a result of paralysis of the vaso-constrictors and the blood-vessels which they innervate (the older and, perhaps, more general view), or it is produced by excitation of the vaso-dilators, as Franck supposes.

Is this paralysis of vaso-constrictors or excitation of vaso-dilators—whichever it may be—of peripheral or central origin? That it is of peripheral origin seems borne out by the experiment of dividing the spinal cord, in which event the vessels continue to dilate under the influence of the nitrite. If the vessels of the head dilate more readily than the others, this fact does not favor the hypothesis that the paralysis (or excitation) is of central origin. The blood-vessels of the head are more dilatible, because their middle membrane is more elastic and more muscular. Finally, the proof that it is all peripheral is that you may cut all the cerebro-spinal nerves, and the phenomenon of dilatation by excitation of the vaso-dilator nerves none the less persists.

Action on the Heart.—The heart's action is considerably quickened, and the number of beats rises to double the natural; the nitrite acts on the pneumogastric center, which is finally paralyzed. At the same time, the force of the heart is undiminished, even if the vascular tension is diminished, which proves that the vascular depression is not an effect of primary enfeeblement of the heart.

Action on the Respiration.—In man one of the most remarkable phenomena from the very commencement is the facility of respiration, whose type, moreover, does not undergo modification; the patient feels that he can breathe more freely. In animals there is, first of all, acceleration of the respirations, which become deeper and more prolonged. With larger doses the respiration becomes slower.

To sum up: in the first period of the action of the medicament the vascular tension is lowered, the vessels are dilated, the action of the heart is very much quickened, the respiration rendered more free and easy. At a more ad-

vanced period, the pressure remaining lowered, the heart becomes slowed as well as the respiration.

Practical Applications.—In its application to the treatment of angina pectoris, nitrite of amyl produces effects which are remarkable and immediate. I have verified this in two patients, one of whom was affected with Corrigan's disease, with severe nocturnal attacks of angina pectoris. This patient occupied No. 20, Ward St. Christophe. From the very first exhibition of the nitrite—three or four drops inhaled from the open palm—the paroxysm ceased, instead of lasting fifteen minutes or more, as was the case when the medicine was withheld.

How does this remedy act? It suppresses pain; it facilitates the circulation, by dilating the blood-vessels; it renders the respiration more free. And all this is done in an instant almost. Nitrite of amyl, therefore, constitutes the most efficacious and the most prompt of the modifiers of the heart, and especially of the circulation. The sanguineous irrigation by the coronary arteries is increased, is accelerated, like that of the other vessels; the cardiac ischæmia ceases, the heart resumes its tasks immediately, and the respiration which before was embarrassed becomes again free. But do not forget that, in going beyond the dose indicated, you expose the patient to the risk of cardiac syncope. Remember, moreover, that the patient, in a sufficiently brief space of time, becomes accustomed to the remedy, so that its good effects become less and less manifest.

Nitro-glycerin.—The physiological effects of this medicament are very much like those of nitrite of amyl. Dr. Murrell, an English physician, was one of the first to call the attention of the profession to this remedy. I have tried it in a few cases, giving internally one or two drops of a one-per-cent. solution; it has seemed to me to give relief.*

Chloral.—Chloral acts very promptly in procuring sleep and in facilitating respiration, but its effects on the circulation are almost nil in these cases. It is not to be depended upon, and I have abandoned its use.

Divers Excitants.—Colin recommends the acetate of ammonium, which is also a favorite with Vignier, in the dose of six grammes.

I shall speak of electricity under the means of prevention. It has no curative power during the paroxysm.

RÉSUMÉ.—Morphine subcutaneously, nitrite of amyl in inhalations (three to four drops)—these are the medicinal measures which seem to me likely to be relied on in the future. Both diminish the intravascular pressure, and thus facilitate the circulation. But there is a physiological contrariety between these two medicaments which seems to demand elucidation. Morphine does, in fact, diminish the intravascular pressure by giving more tone to the blood-vessels, which are made to contract under its influence, but in such a way as to help on the circulation, and thus re-enforce the work of the heart, whose tasks are lightened when

* Mr. Field, of Brighton, England, was the first to describe, twenty years ago, the physiological effects of nitro-glycerin. Dr. Murrell afterward repeated the observations of Field, trying it on thirty-five patients. The action of nitro-glycerin is a little slower than that of nitrite of amyl.—TRANSLATOR.

the auxiliary vaso-motor forces are in their highest state of efficiency. Nitrite of amyl lessens the blood pressure by dilating the vessels, and thus removing obstacles to the free circulation, and in this way lightening the heart's labor. The circulation by the coronary arteries is thus favored by either mode of action, but in a more marked manner by nitrite of amyl. Moreover, the two medicaments assuage the pain which embarrasses the heart's action, and facilitate respiration, which is also embarrassed.

TREATMENT OF ANGINA PECTORIS IN THE INTERVAL OF THE ATTACKS.—Besides the ordinary recommendations to persons suffering from heart disease, spirit-drinkers in general, and smokers in particular, to abstain from customary excesses, it remains to do what can be done to prevent the attacks by hygienic and medicinal means. Jurine advises persons who are victims to this painful cardiac affection to live in the country, to keep as free as possible from all care and excitement, to inhabit a ground tenement, to walk and ride a little every day. This advice would be very good if it were practicable.

The medicinal measures which I employ habitually are: 1. Bromide of potassium; 2. Digitalis; 3. Electricity (hardly habitually, but it deserves mention); 4. Arsenic (of which the same may be said); it is sometimes of use as a vaso-motor tonic, but its action is doubtful.

Hydrotherapeutics ought to be absolutely proscribed.

1. Bromide of potassium determines contraction of the blood-vessels, calms the nervous system (particularly the centers of special sense), and induces sleep; it is a regulator of the peripheral movements of the blood. Under its action the patient becomes less impressionable to the physical and psychical influences which might provoke a return of the paroxysm. But this medicine has the grave inconvenience of producing a debility which is more or less permanent, and can not be continued with impunity beyond a certain time.

2. Digitalis, when the thoracic angor results from cardiac atony or degeneration, presents a real advantage over the bromide; it fortifies and sustains the action of the heart, and is in every way the preferable medicament.

3. Electricity has been applied in divers ways, and in accordance with the different theories which have been put forth as to the nature of the malady. If employed from confidence in the pneumogastric-nerve theory of Eulenburg,* and an attempt be made to galvanize this nerve, you run the risk of arrest of the heart's action; the unfortunate case reported by Duchenne is in proof of this.

If you desire to influence the sympathetic alone, in accordance with the theory of Martin and Hachard, there is a practical difficulty in the way, and, moreover, a physiological heresy lurks behind the theory. There is, in fact, no paralysis of the sympathetic to overcome. The disease is in reality attended with excitation of the cardiac sympathetic nerves, and the coronary vessels, the latter being in a state of *erethism*—there is no paralysis in the case; on the other

hand, there is not even excitation of the sympathetic nerves in general, accompanied by a contraction of the blood-vessels in general. The disease (so far as the nerves implicated are concerned) being partial and limited, how are you going to benefit the pathological condition by electrical currents applied to the sympathetic trunk or plexuses? If it were possible to galvanize the cardiac sympathetic nerves, would you not augment rather than diminish vaso-motor contractility? The subject demands further study.

A CLINICAL LECTURE ON ELEPHANTIASIS ARABUM.

DELIVERED AT THE MEDICO-SURGICAL COLLEGE OF
PHILADELPHIA.

By F. LE SIEURE WEIR, M. D.

CLINICAL PROFESSOR OF DERMATOLOGY.

GENTLEMEN: Among the patients in the waiting-room to-day is one in particular whom I wish to show you, since the case illustrates most beautifully a disease that I had occasion to describe in a recent didactic lecture. At the time of that lecture no case of the kind was to be had for practical demonstration, and, as the lecture came on in the regular order in which the various skin diseases are taken up in the didactic course, I merely went over the ground, as you will remember, intending to take up the subject more thoroughly at some time in the future, when a well-marked case should present itself. Some weeks have elapsed since then, and to-day is the first opportunity I have had of carrying out my design. Nor is this to be wondered at, for the disease is not so common that cases are found every day in the waiting-room. On the contrary, it is a comparatively rare affection. I desire you to observe closely the history and symptoms of this case, as well as the external appearance; but it is to the pathological anatomy and histology that I wish particularly to call your attention.

My assistant tells me that the patient, who is a female, is very nervous, and is reluctant to exhibit herself before so many gentlemen; so, to humor her and not inflict unnecessary discomfort, we will dispense with her presence until it is required to illustrate the external phenomena of the disease.

Elephantiasis Arabum, in the first place, is a disease which has received quite a variety of names—some descriptive of the appearance of the skin, others of the climate supposed to be peculiarly favorable to its development, while yet others have been adopted owing to its resemblance to allied diseases, and so on, almost indefinitely. It is to be regretted that some definite name or combination of names has not heretofore been settled upon to designate the disease and distinguish it from another, for, as it now stands, it frequently happens that an explanation has to follow the use of some of the terms used. Elephant leg has been largely applied to it, and, I must confess, serves an admirable purpose; but it has the disadvantage of being anything but elegant or scientific. Barbadoes leg is another, and was so given through an erroneous impression that the disease was more prevalent there than elsewhere. I need not

* Eulenburg, "Traité des maladies nerveuses," 1878. He describes two forms of the disease, one of which is due to direct excitation of the vagi nerves, the other to reflex excitation of these nerves. He also describes two other varieties of different nerve origin.

say that this, therefore, is a misnomer, since it may occur in almost any section of the globe or under any climate, though it is, to be sure, more commonly observed in tropical countries. *Bucnemia tropica* is open, in a lesser degree, to the same objection. *Spargosis* has been suggested by Mason Good, and adopted by the College of Surgeons of England, but I do not know that it is entirely distinctive, or has any especial claim to recognition from American dermatologists. Elephantiasis has, perhaps, been received more favorably than any other appellation, although it has no other earthly claim than that it suggests the rough, uneven hide of the elephant.

There is no objection to this, however, for the skin of a person afflicted with this disease resembles in no small degree that of the animal named, as you will presently see for yourselves. I say that the name is not objectionable: but this statement must be qualified, for, taken alone, the term is decidedly objectionable. It is only when the word *Arabum* is coupled with it that we have a synonym as complete and free from fault as it is possible to get it. There is another disease the name of which is often confounded with that of the malady under consideration. I refer to leprosy—true leprosy—or elephantiasis *Græcorum*. The two diseases were anciently known as Arabian leprosy and Greek leprosy, which, put in the Latin, give us elephantiasis *Arabum* and elephantiasis *Græcorum*. You will thus readily see the confusion to be caused in the nomenclature by simply speaking of either disease as “elephantiasis.” The simple addition of either word, as the case may be, to my mind, obviates any difficulty, and at once renders the meaning clear. It has been in modern times that this confusion has arisen regarding nomenclature, for among the ancients the disease was known for the most part by one name only—elephantiasis *Arabum*, or the “Leprosy of the Arabians.” In my library is an original work on “Diseases of the Skin,” published in London in 1726, in which the author, Daniel Turner, uses no other name in his crude description, and very possibly he knew no other.

So far, therefore, as we are concerned, there will never arise any misunderstanding as to the disease referred to when speaking of elephantiasis, inasmuch as the suffix will invariably be appended. Allow me to repeat what I said a few minutes ago in relation to the climatic home of this affection: that it is not confined to tropical climates, since it is observed in nearly all quarters of the earth; that it is encountered, though, far more frequently in warm climates, and is in reality a native of the latter. It is especially prevalent in India, the West Indies, Barbadoes, Egypt, Japan, and China. Here in America it is observed much more frequently than it would otherwise be were it not for the fact of our population being constantly augmented from all parts of the world. It is, therefore, probable that most of the cases seen in this country have been imported directly from some one of the hotter countries, or the patients have been at some time, not long before the development of the disease in them, residents of such climates. The cases occurring here in native-born subjects, who have never been in any climate conducive to its development, I believe to be very small in number. The seat of the disease is most usu-

ally the feet, legs, and scrotum, occurring most frequently in the order named. Other parts of the body are, however, not exempt from it, inasmuch as the prepuce and pudendum, and even the head, face, and ears, are sometimes the parts involved.

The doctor has now brought the patient (Mrs. McC.) before us, and, as you probably noticed, she walked into the amphitheatre with a heavy, somewhat rolling tread, putting the feet down upon the floor in a cautious, easy manner, and, by the way, very much after the style of the huge mammal from which the disease takes its name. She is aged forty-five years, and is of Irish birth. As you see, she is somewhat inclined to obesity, but it would require an inordinate amount of adipose to produce the appearance presented in the lower limbs of the patient. She has never lived elsewhere than in Ireland and America, and in the latter country she has been resident for thirty years. Up to four years ago she was perfectly healthy, rarely, if ever, requiring the services of a physician, and in all respects being a fine sample of the sturdy healthfulness of her race. At the time mentioned, however, she experienced an attack of erysipelas which affected both lower extremities from the knees downward. I need not enumerate the train of symptoms attendant upon the erysipelatous lesions, since you are probably familiar with them already. Suffice it to say that, after the force of the local fever and inflammation was expended, resolution did not take place, as you know is ordinarily the case. The parts still remained swollen and somewhat reddish in color, but not markedly so. Bear in mind that the fever and pain and all else had vanished, but the symptoms mentioned.

This state of affairs continued for some months, with the exception, however, that the reddish hue gradually faded away. The parts remained thus *in statu quo* for that length of time, when she was suddenly seized, without assignable cause, with chills, quickly succeeded by fever, and accompanied by some cephalalgia, etc., which was immediately followed by a repetition of the symptoms in the legs—namely, the swelling became more marked, the discoloration returned, accompanied by a feeling of tension, together with smarting, burning, and itching. This remained for some time (several days, probably, though the patient's memory fails her on this point), and was succeeded by the phenomena characterizing the primary attack; that is to say, the symptoms all disappeared but the swelling, which was now more evident than before.

This description of the attacks occurring at the commencement of the disease serves for all subsequent ones; they have been nearly all alike, presenting the same symptoms, running the same course, and every attack leaving the parts larger than before. These seizures have occurred at varying intervals from that time up to the present; how many I do not know, nor does the patient herself.

During the interval between the later attacks the redness has not disappeared as it formerly did, but, on the contrary, increased, thus showing the capillary network to be largely hyperæmic. The redness is diffused generally over the surface of the skin, but at different points, for some inexplicable reason, the discoloration is intensified, and proclaims

itself in the form of purplish-red blotches and nodules, the edges of which are not well defined. Exposure to cold weather or wetting the feet results in a fresh onslaught of the inflammation, and always leaves the part more hypertrophied than before. At the time of the seizures the lymphatic vessels become hard and tender, and run as well-defined red cords along the limbs. The lymphatic glands also participate in the general disturbance. There you have the history of the case. By inspection, we see that both legs are enormously enlarged from the knees downward to the ankles, where a roll of hypertrophied tissue hangs over feet so deformed by the disease as to be scarcely recognizable.

The rolls at this point, as well as the rough tubercles (which so strikingly resemble the pachydermatous covering of the elephant or rhinoceros), consist of enormously indurated subcutaneous cellular tissue, the direct result of repeated attacks of inflammation of those parts. The mass has a hard, dense feeling, as though handling a thick piece of rubber. Pinching conveys the same impression, for the parts are too dense to yield readily, and, when released, resume their former shape. There is no tenderness on pressure, and there is every reason to believe that sensibility is not diminished. The patient's general health is good; the appetite is the same; the natural functions of the body are regularly performed; and she is just arriving at the menopause.

She complains of no special pain in the parts, but, instead, a dull, indefinable heavy ache, due, I think, to their weight.

It is, however, to the pathology of this elephantoid malady that I desire to draw your particular attention, for herein shall we find the secret, if it is to be found at all. I need not say to those of you who have given any especial attention to pathological research how much may be learned through this channel, for no man can be employed in this field and not be impressed with the mighty wonders lying hid away, only awaiting the magic stroke of the anatomist's knife and the microscope of the histologist to be laid bare to the intellect. Since pathological histology has come to be recognized as playing so important a part in the science of life, many hitherto ill-understood diseases have yielded up their secrets so long concealed from us beneath a multitude of (in many cases) misleading symptoms. I can not too highly eulogize this peculiar branch of study, realizing as I do how closely it is allied to the successful comprehension of disease in all its fantastic forms, and the consequent successful treatment of the same. My colleague, the head of the department of pathology, doubtless becomes warm upon his subject; but, while I fully share his just enthusiasm, it behooves me to proceed to an explanation of how this science aids us so mightily by applying it to the case under consideration.

The disease is essentially classed nosologically under the head of hypertrophies.

The lymphatic system is the primary seat of the affection, and the first stage is inflammation. It naturally follows that, if we have repeated attacks of inflammation concentrating in a given locality for any length of time, the

intervening time between the attacks being comparatively short, some slight influence will be exerted upon the lymphatic vessels traversing the part; and, if the attacks be continued, these same vessels will consequently become more or less obliterated, and their functions thereby impaired to the extent that the lymph, which it is their office to convey away, is of necessity deposited in the substance of the subjacent tissues.

From this accumulation the tissues become impacted, and hypertrophy is the direct result. When a deposit of lymph had once taken place in this case, the subsequent erysipelatous attacks I believe to have been caused quite as much by the abnormal excitation under which the tissues labored as by the existence in the blood of the specific poison of erysipelas itself; and, further, that this self-same poison, now generally admitted to be peculiar to erysipelas, would not assert itself so frequently and without apparent cause were it not for the constant incentive (in the form of the hypertrophied tissues) to a fresh outbreak.

The hypertrophy becomes more and more intense under the repeated attacks of inflammation, until it is communicated to the layers of the skin adjoining that in which the primary deposit took place, and at last the epidermis, corium, and subcutaneous cellular tissue are all involved, while the blood-vessels are distended and forced to do an amount of work largely in excess of that which they are ordinarily called upon to perform.

The knotty and rugose appearance of the superficial layer of the skin is due to the accumulation of a prodigious number of epithelial cells; and it is this latter feature, together with many of the other conditions mentioned, that has induced some very acute observers to declare elephantiasis Arabum and scleroderma identical, since in the latter affection the same characteristics are noticeable.

I hardly think them identical, notwithstanding the strong argument of the analogy between them pathologically. The two diseases are probably distinct and separate, and they furnish a well-marked example of how nearly allied diseases of the same class may be.

Free nuclei, cells, and fibrous bands, all in process of development, are observable everywhere, while fat cells are numerous, especially about the muscles. The latter are usually atrophied. The nerves—that is, the larger ones—are somewhat flat in shape, and occasionally enlarged. This is not, however, an invariable accompaniment. If an incision be made into an elephantiasic leg, the knife penetrates through integument of leather-like consistence, grating harshly and even requiring an effort, so great is the density of the part, and is frequently followed by an escape of lymphoid fluid, the presence of which is what gives rise to pitting on pressure in the earlier stages of the disease.

I have now given you a few of the leading features of the morbid anatomy of elephantiasis Arabum; and if, aided by your note-books, you will grasp them, as I am sure you can, you will have gained a considerable step in the study of dermatology, difficult though it is thought to be.

As to the etiology there can be but little said, since but little is known. In the present case erysipelas ushered in the initial attack, and to it, in the absence of any other as-

signable cause, must be attributed the disease. Nor do I see any objection. It is a fact worthy of notice that erysipelas in the majority of cases precedes an attack of elephantiasis Arabum; but that such is the invariable rule is not true. Other causes have been advanced, it is true, but none have so plausible a backing. There has never been any special effort made, to my knowledge, to ascertain the reason why erysipelas is so frequently a prodrome—if the word will apply. The books are altogether misty on the ætiology of the malady.

The diagnosis offers no difficulty.

I will venture to say that none of you now present ever saw any other disease that resembled this one before you to-day. The very shape, together with its appearance, is simulated by no other disease, and is then conclusive.

The prognosis is not, as the rule, favorable, for the disease lasts a varying length of time, possibly through life. Our patient has been a sufferer for four years, gradually getting worse, and with every prospect, as the case now stands, of continuing so.

TREATMENT.—The disease is amenable to treatment to the extent of amelioration; and in this mitigated condition—in the cases where mitigation is possible—the affection continues to the end of the chapter. But very little remains to be said concerning the treatment, for it is unsatisfactory. The most encouraging results have been obtained from the use of external applications. Cold lotions, hot fomentations, frictions, rest, pressure, and blistering have each been used extensively, the result being in the main but indifferent, though occasionally a marked diminution has been observed. In connection with external applications, I should think prolonged medicated baths might be serviceable, though, perhaps, not any more radical than the other means just spoken of. I have never tried them.

Internally, the salts of quinine and potassium, and mercury in various forms, have all been tried, and with success in not so large a ratio as with external means. A judicious combination is advisable in most cases as being productive of the best results.

There is, however, one method which I have not yet mentioned—namely, ligation of the main arterial trunk. This measure is extremely heroic, but has yielded better things than any other; it is, moreover, based upon good, sound anatomical and physiological principles. One observer, whose name has escaped my memory, has rightly said that the ligation of the principal vessel supplying a part has different effects upon normal and abnormal structures. Lest you do not comprehend my meaning, I will repeat that tying the main artery in a sound limb has a different effect from what it would have were the limb diseased.

I think I make the quotation very nearly *verbatim* when I say that “the activity of absorption, as a general rule, is in inverse ratio to that of circulation. And when the force of circulation is diminished, absorption is usually more energetic. The process of absorption frequently goes on of its own accord if once started.” In other words, if, in this case, we were to ligate the femoral artery, absorption would go on more rapidly than if the same operation were per-

formed upon a sound limb. Ligation is not always attended with success, nor anything like it; on the contrary, no change whatever has resulted from such an operation in more cases than one.

I should be very chary about resorting to this remedy, notwithstanding that it holds out more hope than any other known means. The dangers are manifold: gangrene is liable to follow, in defiance of collateral circulation (which my learned colleague, Professor Oliver, has doubtless freely demonstrated to you); pyæmia may occur, though this is not to be feared like gangrene, for the occurrence of the latter means amputation; and, lastly, alarming hæmorrhage may occur from what would be in the normal state small branches, but here greatly enlarged. Cutting operations are best avoided, especially if the affected part is the scrotum. Here frightful hæmorrhage has followed an attempt at extirpation by the knife. I recall a somewhat unique and remarkable instance of amputation of the scrotal mass by a clamp-like apparatus, in which one hundred and thirty-six cases were operated upon with most gratifying results.* The clamp was composed of two parallel bars, with a screw at each end, by means of which the upper bar could be screwed down tightly when applied to the neck of the tumor. The upper has a slight depression, or rather excavation, in the center, to accommodate the penis and prevent it from being crushed. The whole apparatus is very simple, and answered an admirable purpose, as evidenced by the fact that of the hundred and thirty-six operations only two resulted fatally. A similar clamp is suggested, I believe, in former editions of Druitt's “Vade Mecum.” The smallest of the tumors weighed seven pounds, and the largest eighty pounds. There were two which attained the latter weight, one of which measured fifty-four inches in circumference, the other about forty inches.

The account (which I would advise you to read carefully) is not without its moral, since it shows what can be accomplished when we are put to the test. Here was a surgeon who lived in that out-of-the-way corner of the world, the Samoan group of islands, who had never seen an operation of this kind, if, indeed, he ever had seen a case of the disease before, and who, when the necessity arose, was equal to the emergency, and constructed his own appliances, or, at least, caused them to be constructed according to his suggestions, and by their aid boldly attacked the enemy with the brilliant results recorded. The moral is obvious: always be prepared, for you never know at what moment you may be called upon to exhibit your tact and skill; and promptness and ability to cope with danger you will find most invaluable to you in your professional life hereafter, while to fail is not only to the disadvantage and oftentimes peril of your patient, but disastrous to your reputation. Although I should not hesitate to cut down upon a main arterial trunk and tie it, in a case where I thought the constitution equal to the shock and subsequent exhausting drain of any kind upon the system, I am loth to advocate anything of the sort in this case, for the patient's vital powers are not sufficient to brave the possibilities, not-

* Turner, “New York Medical Abstract” (from Glasgow “Medical Journal”), July, 1882.

withstanding her stout figure—in fact, that is just one potent reason against any such procedure. In the second place, she will not consent to any operation of a “cutting” nature, so that that disposes of the matter very effectually. In a recent communication received from Professor A. C. Post, of New York, he informs me that he has used the actual cautery (*ferrum incandescens*) in *dermato-cellulitis* with most gratifying effect, “the patient being, in every instance, well pleased.” This, so far as I know, has never been applied in *elephantiasis Arabum*, but, reasoning *a priori*, I think that its use in the latter disease might be productive of much benefit. If it is possible to obtain the patient’s consent, I will apply this remedy in the present case, and in your presence.

For the present, however, I will apply this thin rubber bandage (somewhat on the style of Esmarch’s), which is about three inches wide, and sufficiently long to reach from the distal extremity of the toes to the knee. This I now apply, beginning at the toes and moving upward, drawing the bandage moderately tight as I go, and thus pushing the blood before it. You doubtless wonder why I had the woman placed upon her back before commencing to bandage: it is to get the benefit of gravity; and this desired end is more completely attained by having my assistants to hold the leg in an elevated position.

I am careful, as you see, not to make too much traction lest I deprive the parts of too much blood. Spiral turns are all that are necessary in applying an apparatus of this description, especially where the limb, as in this case, is of about a uniform size from foot to knee. I now tie the two ends of tape, attached to an eyelet in the extremity of the bandage, around the leg, and thus secure it from unwinding. But one leg will be bandaged at a time until we note the effect. Already, she tells us, the leg feels better. By that she means that the immense rolls of indurated skin have now support, and, in consequence, she does feel better.

We will have her here again shortly, at which time, should we be able to gain her consent, the iron will be used.

Original Communications.

THE STATUS OF THE MEDICAL PROFESSION IN THE STATE OF NEW YORK.

By HENRY G. PIFFARD, M. D.

Fourth Article.

At the annual meeting of the Medical Society of the County of New York, held October 25, 1880, its Committee on Ethics made the following report: *

“Almost without an exception, therefore, the work of the committee has been confined to complaints against members of the society for public advertising, or methods that are regarded as at variance with the spirit, if not the letter, of that

portion of the American Code of Ethics embraced in Chapter II, paragraphs three and four.

“The committee approached this well-known field of action, where an almost ineffectual skirmish has long been kept up, with feelings of great uncertainty as to what the result of their efforts would be, and with a desire to perform their unpleasant duty without giving unnecessary offense to any. The committee, although to some extent shielded from personal attacks by its official character, has been unable in all instances to perform its duties without censure from individuals with whom it has been in communication; and in other instances, where requirements were made under the committee’s interpretation of the law, it has encountered firm opposition. Previous to this committee’s appointment, efforts had been successful in securing the withdrawal of physicians’ mineral-water testimonials from the public press, but it was well known to the committee that all attempts to suppress those still appearing in the medical journals had been in the main unavailing; indeed, these futile efforts were treated as an encroachment on the rights of those concerned.

“The society, when appealed to on this subject at a meeting held April 22, 1878, adopted a resolution clearly expressing its disapproval of the practice of giving certificates to be used in bringing to notice ‘any drug, nostrum, mineral water, wine, or other proprietary article intended to be used as a medicine or remedy in disease, or to any patented instrument or appliance that is intended for medical or surgical use.’

“This resolution, which, morally at least, had all the force of a by-law of the society, was at the time of its adoption brought to the notice of every member of the society. The effect, however, was not what had been expected, and the commercial pages of the medical press still teemed with advertisements of trade-marked preparations, etc., bearing the sanction of medical men. . . .

“The committee, after mature deliberation, being encouraged by the success others had already attained, and fortified by the resolution of the society above alluded to, thought that it was clearly their duty to make another appeal to those who still considered that they had a right to give their sanction to the articles under consideration in a manner objectionable to the profession in general. The committee, therefore, adopted the following at a meeting held January 7, 1880: ‘Resolved, That, in view of the fact that these certificates are offensive to a majority of the profession, and that their continuance is an injury to professional tone, the Committee on Ethics respectfully requests the gentlemen concerned to take measures to have them discontinued.’ This resolution, together with that adopted by the society, was printed in the form of a circular, and copies of it were sent to all whose names had been reported to the committee, with a request that they would signify to the committee what course they intended to pursue in the matter. The total number to whom the circular was sent did not, perhaps, exceed two dozen.

“As a result of this action, a very small number signified their intention to withdraw the objectionable testimonials, and the committee has been informed that they have done so. In a few instances, letters in vindication of certificate writing were received, but it is believed that the position assumed in defense is not tenable, for in the advertisement of lactopeptine, for instance, the virtues of the remedy are extolled in a manner rather to arrest the public eye than instruct the physician; and this of a preparation where the method of manufacture is kept secret, and where the copying of its name by any one would render him liable to prosecution. The indication of the constituents of this preparation does not relieve it from the objection held against trade-marked and proprietary articles.

* I omit such portions of the report as have no bearing on the present question.

"The greater number to whom the circular was sent, however, failed to respond to the committee's request, and their certificates continue to appear.

"It will thus be seen that the committee has advanced this work but little, for, so long as any member can permit of the publication of these certificates with impunity, the majesty of the codes of ethics is not maintained. And, now that the society has continued to experience defeat in this matter, it may be well, before entering the contest again, to inspect its position and strength. The committee has, therefore, made a careful examination of that portion of the American Code of Medical Ethics and of the System of Medical Ethics of the Medical Society of the State of New York bearing on this subject, and it seems to it that, although their provisions may have been sufficient for the time when they were adopted, a gradual transformation in the character of the abuses alluded to has taken place, and, instead of secret remedies, there has grown up the proprietary and trade-marked article, which requires the investment of a large amount of capital. Secrecy has ostensibly been removed as to the constituents of these goods, but their manufacture or imitation is successfully prevented by patents and trade-marks. That they owe their chief value to professional testimonials and skillful advertising may well be believed. The committee has failed to find anything in the codes referred to sufficiently explicit to give them plenary power to take further action. If, therefore, the society desires to prevent its members contributing to trade interests in the manner above alluded to, and thus injuring its own, it has ample power under the State statutory laws to make the resolution of April 22, 1878, a by-law of the society. The experience of the committee leads it to believe that no other course will accomplish the end desired. . . .

"In this connection, it may be pardonable for the committee to state that its experience during the past year has, in a forcible manner, demonstrated the inadequacy of the present codes of medical ethics to the existing demands of the profession. The code adopted by the American Medical Association thirty odd years ago has in many respects become obsolete; what were deemed offenses then are no longer regarded in the same light. *Per contra*, the ingenuity of man has developed practices which were unknown when the codes, national and State, were established, and hence were unprovided for. The code of the American Medical Association contains a mass of sentimental advice which, together with its moral platitudes and verbiage, would seem to suggest the necessity for its revision. Our own System of Medical Ethics, which the State society adopted in 1823, and which has since been subjected to but few alterations, is, perhaps, even more obsolete than the code above alluded to. The profession is now in no sense guided by these codes; nor does it seem desirable to hold it together either by the regulations that pertain to trades-unions, or by the moral platitudes of existing codes, but it rather requires for its wholesome government clear and business-like regulations, backed up by our ample statutory laws, leaving the matter of moral maxims and precepts, as well as personal manners, to the social conditions that surround the individual."

This report was signed by Drs. Samuel Sexton (Chairman), James R. Leaming, W. M. Polk, J. D. Bryant, and Clement Cleveland, Secretary.

The foregoing was printed, and distributed to the members of the society.

At the annual meeting of the Medical Society of the State of New York, held February, 1881, the President of the society, in his Inaugural Address, called the attention of

the society to the necessity for a change in the code of ethics, perhaps the need for an entirely new one.

The committee to whom the President's address was referred reported the following resolution:

"Resolved, That a special committee of five be appointed by the President, to be designated a 'Committee on the Code of Ethics,' whose duty it shall be to consider the whole question of desirable changes in the code, and who shall present to the society, at the session of 1882, such suggestions on this subject as their observations and investigations may direct." This resolution was adopted by the society, and a committee of five was appointed. Of the *personnel* of this committee the following may be stated: Three of its members were chosen from among the older members of the society and the profession, and two from among those who had been in practice between fifteen and twenty years. Three of the members had been presidents of the society, and the other two had served on important standing committees. Three were from the northern, western, and middle portions of the State, and two from the city. Three were general practitioners, and two were specialists. From this it would seem that the various interests involved had been carefully provided for. The committee gave the subject with which they were charged careful and laborious attention during the year that was allotted to them. The views of the different members were in part elicited and circulated by correspondence, and the views and feelings of many of the more prominent, and also of the more obscure, members of the profession were sought. After a pretty complete knowledge had been obtained of what appeared to be the prevailing sentiment of the profession throughout the State, the committee, setting private business aside, devoted two entire days to the matters under consideration. The first conclusion arrived at was, that, if the profession of the State desired a code, one should be reported that should be clear and distinct in its meaning, and one that could be enforced when necessary. The second conclusion was that the code should contain nothing that was already provided for by the laws of the State, or by such moral laws as all, whether Christian, Jew, or infidel, considered binding. This narrowed the matter to the formulation of such rules as seemed to the committee most likely to be in harmony with the sentiments of the thoughtful members of the profession, and to conduce to the best interests both of it and of the public.

The two most important sections of the code were, first, those relating to the matters which the Committee on Ethics of the New York County Society had brought to the notice of the profession, and, second, those which related to the question of consultations. In dealing with this matter, the committee carefully examined the American code, and found, as had been pointed out by the New York County committee, that it did not fully cover the ground. They, therefore, added several supplementary clauses, which made the completed article read as follows:

"It is derogatory to the dignity and interests of the profession for physicians to resort to public advertisements, private cards, or handbills, inviting the attention of individuals affected with particular diseases, publicly offering advice and medicine

to the poor without charge, or promising radical cures; or to publish cases or operations in the daily prints, or to suffer such publications to be made; or, through the medium of reporters or interviewers, or otherwise, to permit their opinions on medical or surgical questions to appear in the newspapers; to invite laymen to operations; to boast of cures and remedies, or to perform other similar acts.

"It is equally derogatory to professional character, and opposed to the interests of the profession, for a physician to hold a patent for any surgical instrument or medicine, or to prescribe a secret nostrum, whether the invention or discovery, or exclusive property, of himself or of others.

"It is also reprehensible for physicians to give certificates attesting the efficacy of patented medical or surgical appliances, or of patented, copyrighted, or secret medicines, or of proprietary drugs, medicines, wines, mineral-waters, health resorts, etc."

We believe no open objection has been made to any of the provisions of the foregoing sections, except with reference to the matter of patenting surgical instruments. It is claimed by those who advocate the propriety of patenting instruments that there is really no difference between that and taking out a copyright on a book. Personally, we can not regard the matter in that light; for, if this be admitted, a parity of reasoning would indorse the propriety of patenting medicines.

In the second important matter connected with the revision of the code—namely, the consultation question—the committee felt that the gravest responsibility rested on them. In dealing with it, they believed that a correct and lasting solution would alone be reached by discarding sentiment and their own personal preferences, and considering the matter from the stand-point of actual fact. It was perfectly well known that consultations between regular physicians and homœopaths were of frequent occurrence. It was also perfectly clear that the disposition to prosecute and discipline offenders for this breach of the code had disappeared. The last case of discipline known to the committee was the Gardiner case, fifteen years ago. It was also deemed probable that, since the homœopaths, by formal resolution, had repudiated their "exclusive" position, and had thus escaped the letter of the code, convictions of offenders would be exceedingly difficult; and that, if a society should convict a member and suspend or expel him, the courts would, on technical if no other grounds, inevitably reinstate him; and a society repeating such action would probably become amenable to the charge of contempt of court, with its attendant consequences, and possibly liable, also, in civil damages to the aggrieved party. It was almost morally certain that no prosecutions of this sort would be undertaken, except by some indiscreet person, for purposes of gratifying private malice. The heresy-hunters of a preceding generation had mostly disappeared, and there were apparently none left who felt it their duty to act as public prosecutors. It was perfectly clear to the committee that the restrictive clause of the code availed only with those who felt themselves in honor bound by its apparent spirit, while it left all others to do as they pleased, free from any anxiety as to the consequences.

Under these circumstances the committee had but two

courses before them—one of which was the preparation of a consultation clause so carefully and tightly drawn that escape from conviction would be impossible, or else to recommend the abolition of all restrictions on the subject, leaving the matter to the individual consciences of all those who were interested. If the first course had been adopted, there is not a shadow of a doubt that the courts would have pronounced it "*contra bonos mores*," and void. The people of the State, as well as the legislators, had already become sufficiently indignant against the profession for assuming an attitude that appeared to them bigoted, intolerant, and inhumane. The rule of the American Medical Association was generally regarded as iron-clad, admitting of no exception; and cases almost without number were known to the committee in which medical men had refused consultation assistance under circumstances that laid them open to the gravest charges of inhumanity, the only excuse given being that the rules of their order forbade them doing otherwise. The code of the American Medical Association, in its true and intentional meaning, is rigid and inflexible; no matter what may be the occasion, a physician meeting or consulting with an "irregular" was liable to discipline. Dr. Flint's humanitarian construction is not warranted by the language.*

The committee, therefore, deemed it both useless and unwise either to retain the rule of the American Medical Association or to recommend the adoption of a stricter one.

The medico-political aspect of the question also received consideration, and from two points of view. In the first place, the effects of the exclusive attitude of the profession on the homœopathic question were duly weighed, and it was the unanimous opinion that the consultation clause of the code of the American Medical Association had, more than any other one agency, assisted the homœopaths to obtain their present position in the estimation of the public, and the abolition of this clause was the first step to be taken if it were desirable that the people should again estimate medical men according to their individual merits, rather than as upholders of this or that doctrine. In the second place, those who had interested themselves to obtain legislation on medical subjects intended to improve the status of the profession of the State were frankly informed that no relief might be expected from the Legislature so long as the profession was at war within itself.

* The Academy of Medicine in this city was certainly the strong hold of the few that were left who appeared to have the disposition, if not the energy or courage, to attempt to re-establish the old order of things, and who, if they could have their way, would, as in the past, lay down for the medical profession strict rules relative to the medicines and doses that should be prescribed, books that should be read, and persons that should be acknowledged as acquaintances. When the writer commenced the practice of medicine it was considered "off-color" or irregular for a physician to prescribe medicine as an antipyretic, to read or have in possession a homeopathic "brandy" book, or to have even a speaking acquaintance with a homœopathic practitioner. Most of those who then ruled the profession have passed to that undiscovered country from whose bourne no traveler hath returned, but the few survivors still maintain their ancient bitterness and hate, and, under the plea of allegiance to the American Medical Association, have joined with those who for other reasons seek to control the affairs of the profession in this State.

When intestine differences were healed, the State would be only too glad to do what it could to elevate and improve the material condition of medical men; but, so long as there were factions, the State would take no action that might perhaps aid one to the detriment of the other. These reasons alone should, in the writer's judgment, have been sufficient to decide the question at issue, but there were others which appeared to the committee to be even weightier. The relation of the profession to the welfare of the community was an element that could hardly be overlooked. To exemplify this point briefly, it may be assumed that the only instance in which a homœopath would desire or ask for a consultation with a regular would be when in the treatment of a given case he had exhausted his own resources, and the patient still remained uncured. Under these circumstances, duty to his patient certainly demanded that he should seek advice and counsel from such sources as in his judgment would be best able to supply them. To this end he solicits the aid of a Thomas, a Flint, or a Sayre, believing that their larger experience in certain departments may throw a clearer light on the pathology of the case, or may enable them to suggest a more successful method of treatment than the one previously pursued. If, now, these gentlemen believe that their own methods are not superior to those commonly pursued by homœopaths, or that their skill is less than that of the physician who seeks their aid, they certainly have valid excuse for declining a consultation. If, on the other hand, the consultant has reason to believe that his experience or skill may contribute somewhat to the recovery of the patient, it would certainly seem that his duty to the individual, and, in a wider sense, to the community, was perfectly clear. To the performance of this duty there has heretofore been but one obstacle—the consultation clause of the American code.

Still another aspect of the question presented itself—namely, the right of a society to lay down any restrictive rules for the guidance of its members which interfered with the free exercise of their talents and abilities in the pursuit of their calling. It may be conceded that there exists in every organized body a necessity for certain rules and regulations relative to its organization and continuance; and it may be contended that individual members should yield some of their personal rights, if the general body to which they belong will be benefited thereby. The present question, however, does not appear to fall within either category, as it certainly will not be claimed that, if A (regular) consults with B (homœopath), C (regular) is injured thereby, or that the fellow-members of A and C receive any detriment as a body from the action of A. We, therefore, fail to see any good reason why A should be restricted in the matter of consultation when either his sense of duty or his inclinations or interests are at stake; and a rule that does so restrict him belongs to the class of rules which American citizens have always regarded as opposed to that liberty of action which is referred to in the Declaration of Independence, and guaranteed by the Constitution of the United States. It is a rule utterly opposed to the principles that underlie the national and State governments of this country.

The foregoing may be regarded as among the moral aspects of the question, and those which most certainly should be the first to be considered; and the committee were of the unanimous opinion that ordinary morality and the welfare of the community demanded that the old rule should be abolished, and the matter of consultation left to the good sense and conscience of each qualified practitioner.

The question of expediency next demanded attention, and more especially in its relation to the sectarian bodies. Would the proposed action aid them to maintain their antagonistic attitude? Or, on the contrary, would it not, by removing the chief excuse for their existence, tend to their gradual extinction? The committee were unanimously of opinion that such would be the effect of the contemplated action.† It must not be supposed, however, that the committee overlooked the relations which the State society bore to the American Medical Association. On the contrary, these were considered most carefully and exhaustively; but, since much misapprehension exists as to the relationship between this body and the various societies which are represented in it, we will briefly state the facts:

The American Medical Association is a voluntary and self-constituted body, without charter or any form of incorporation, amenable to no other authority than its own will, and without power to exercise authority over any other body. At the time of its organization it adopted certain rules by which its future membership should be regulated, which rules have, from time to time, been amended and changed. The association indicates the kind of societies from which it will receive delegates,‡ and the terms on which said delegates will be admitted.* The acceptance of these terms by the various State and other societies simply permitted them to be represented, and to take part in the proceedings of the association.

The association is also composed in part of what are known as "permanent members," namely, persons who once or oftener have served as delegates, and who, in virtue of this fact and an annual payment of five dollars, become entitled to assume the designation.¶ The permanent members, however, do not enjoy equal powers and privileges with the delegates. They are entitled to seats, and, in a qualified sense, are allowed a voice in the proceedings. They can not, however, give practical force to any views that they may hold on topics under discussion, inasmuch as

* The doctrinal changes that had occurred in both the homœopathic and regular schools during the past fifteen years were so great, and in such converging lines, that there was no longer any sufficient *raison d'être* for the continuance of societies whose coherence depended on dogmatic or doctrinal peculiarities, their only real bond of union being one of political defense against the aggressive attitude of the regular profession.

† The very decided confirmation of this opinion by recent events will be shown later.

‡ These are permanently organized State medical societies, and county and district societies entitled to representation in the State societies.

§ The adoption of the association's code of ethics.

¶ At one time a single payment of five dollars and attendance on a single meeting of the association were the only requirements for permanent membership.

they are not permitted to vote. It will, therefore, be seen that the practical management of affairs is taken out of the hands of the older and more experienced members and left to the judgment of those who are younger, many, if not most, of whom visit the association for the first time ready to become the veriest clay in the hands of some wily and adroit manipulator.*

It will be seen from the foregoing that the American Medical Association is not in any sense a confederation of State and dependent societies, united by mutual pledges to each other, as is the case with the States forming the Federal Union, but simply a body composed of such societies as find it to their inclination or interest to conform, for the time being, to certain rules and regulations. If, therefore, a State society should place itself in a position that would prevent further continuance of its connection with the association, such action can not be considered as a *secession* in the same sense as a withdrawal of States from the Union would be. It is not a violation of any promise or pledge, but simply the severance of a connection which, in this instance, the committee believed was at the present time, and under present circumstances, a source of injury to the profession of the State.

In the light of these facts and conclusions, the committee decided to report the following for the consideration of the State society:

"Members of the Medical Society of the State of New York, and of the medical societies in affiliation therewith, may meet in consultation legally qualified practitioners of medicine. Emergencies may occur in which all restrictions should, in the judgment of the practitioner, yield to the demands of humanity."

As the subsequent sections of the State code have not been specially criticised, we will not quote or make further allusion to them.

After the committee had agreed on their report, the question of publishing it in advance of the meeting was considered. The committee would have been glad to give it the fullest publicity, but they were without authority so to do. It would have been contrary to custom, and an act of disrespect to the society, for any of its committees to give to the public a contemplated report in advance of its presentation to the body that had ordered it. It was thought proper, however, to show it to some of the ex-officers of the society, and especially to those who, it was supposed, might have opposite views to those of the committee. The writer was responsible for the use of but a single copy

* The constitution of the New York State Society is essentially different. In this body the delegates, in accordance with the statutes of the State, are elected for four years, one fourth of the total number being elected annually and one fourth retiring. At every meeting, therefore, there will be those who are serving in their fourth year, others in their third, and others in their second, while but one fourth of the entire number of delegates can by any possibility be men without experience in society matters. In addition to the delegates, the permanent members constitute an important factor in the society. They are chosen from among such delegates as have served three out of their four years of service, and the number that may be elected annually is limited by the statutes of the State. Permanent members have both voice and vote.

in this manner. It was shown to an ex-president of the society, who, in a letter received the following day, commented on it as follows:

"If the spirit of the new code, which is proposed, and the spirit of the resolution which you read to me as unanimously adopted by the Royal College of Physicians of London, had governed the profession forty years ago, homœopathy would never have attained an elevation, in the opinion of any of the educated or cultivated portion of the community, as an antagonistic school in medical science. Both the profession and the public would have been saved much evil."

The action of the State society on the report of the committee and the events that followed will be considered in our next.

REPORT OF TWO CASES OF SYPHILIS OF THE LUNGS.

By DR. H. RAPHAEL,

ATTENDING PHYSICIAN FOR DISEASES OF THE GENITO-URINARY ORGANS AND SYPHILIS, BELLEVUE HOSPITAL, OUT-DOOR DEPARTMENT.

CASE I.—C. B., aged thirty-eight, merchant. First consulted me for syphilitic ulceration of the larynx. On examination with the laryngoscope, the entire right side of the larynx was found to be ulcerated, involving the right vocal chord; the left was also thickened and red in color. As a consequence, he was unable to talk louder than in a whisper. He also presented the characteristic copper-colored patches on the skin peculiar to syphilis, enlargement of post-cervical and other glands, and a node on the right tibia and left clavicle. The primary lesion on his penis had been cured some five or six years previously. He was under treatment at various times, but never followed out a systematic course, ceasing to take medicine as soon as improvement commenced. In January, 1879, he again consulted me for a violent dyspnea, accompanied by a dry cough, which came on suddenly, giving him no rest by day or night, and compelling him to absent himself from his business. Of late he had been losing flesh very rapidly, and that, together with his cough, alarmed his friends very much. On percussing his chest, a distinctly dull, circumscribed spot was found on the right side, in the vicinity of the nipple, and, on auscultation, that part of the lung was found to be impervious to air, no respiratory sounds whatever being heard over the corresponding part. Some three weeks' active treatment with small doses of mercury and tolerably large doses of iodide of potassium and iron and other tonics was necessary to restore him to a condition to enable him to attend to his business. His dyspnea and other chest troubles disappeared, and the respiratory murmur was again audible all over the thorax; the nodes and the other syphilitic phenomena were also immensely improved.

CASE II.—Charles A., aged thirty-three, clerk. First contracted a chancre some five years before he came under my care. For that he was treated while he was out West. About a year subsequent to that an eruption appeared on the skin, for which he was treated by the administration of corrosive sublimate hypodermically. The result of this method of treatment in this case was not satisfactory, for

the patient not only was not cured of his syphilis, but indurated ulcerations formed at the places of the subcutaneous injections of the mercury. By the use of inunctions and mercurial vapor-baths the eruption and indurations gradually disappeared, leaving only the well-known copper-colored spots and cicatrices at the places of the ulcerations. Two years later he had an attack of iritis of the left eye, accompanied by intense osteocopic pains, which were always aggravated toward evening. From this attack he recovered under the use of large doses of iodide of potassium internally, and atropine to the eye. Three years after that he had an attack of pain in the chest, cough, and dyspnea, evidently due to some morbid process or deposit in the lungs, characterized by distinctly circumscribed dullness on percussion and the total absence of respiratory sound. He was again given a course of mercury (inunctions), and large doses of iodide of potassium internally, with the result of not only improving his chest trouble, but his general condition, so that he was soon able to resume his usual vocation.

In both of these patients there were present, in addition to the characteristic features of syphilis, most of the subjective and some of the objective symptoms of phthisis, namely, dullness on percussion over a circumscribed area, absence of the respiratory murmur, emaciation, dyspnea, short, hacking cough, etc., etc. Both had been told that they were suffering from phthisis, and the question naturally occurred whether the phthisis, if it could be considered in that light, was a complication of the syphilis, or these symptoms were simply occasioned by the morbid syphilitic deposits in the lungs. This pathological condition may be originally one of two forms, either as a diffused or a circumscribed deposit; sometimes, however, both forms are found combined in one individual.

In the diffused syphilitic disease of the lungs the diseased parts are generally of a firmer consistence, heavier, and of smoother surface. The infiltration may be found in one or both lungs, or only parts of each. The infiltrated parts are almost totally airless, grayish-red or grayish-yellow in appearance, smooth, homogeneous, with slightly opaque secretion. The bronchi are generally patulous, and contain a considerable amount of purulent secretion and but little air. The mucous membrane of the part is pale in color, smooth, and in the larger bronchi somewhat thickened; the bronchial glands are almost always enlarged.

Often the entire lung, especially in congenital syphilis of the new-born, has a peculiar pale, whitish color, a condition which was first described by Virchow as "white hepatization of the lung during intrauterine life." Hecker, however, was the first to regard it as a result of syphilis. As we will see further on, the diffused syphilitic infiltration is more frequently found in the new-born than in the adult; the nodular form is the most frequent kind encountered in the latter. Now and then we see near the diffused infiltration, near the periphery, circumscribed knots of the size of a pin's head up to that of a cherry, grayish-yellow in color, somewhat prominent nodules, which were first described by Depaul, and subsequently by Lebert and others.

The histological process in the diffused syphilitic infiltration consists essentially in a thickening of the interstitial

structure. The interlobular as well as the connective tissue lying between the alveoli are permeated by numerous spindle-shaped and roundish cells, and this exuberance seems in reality to start from the walls of the vessels and of the bronchi; especially of the former are the endothelial cells found to be enlarged, often containing numerous granules; at the same time white blood corpuscles accumulate in the altered vessels, by which the capillaries may become transformed into solid cellular or fibrous strings; on the larger vessels, relatively larger exuberations of the adventitial connective tissue take place. Whether the lymphatic vessels become diseased in the same manner as the blood-vessels it has not been possible to show. Through the interstitial exudation the alveoli become compressed, and within them the epithelial cells, which have in greater part desquamated, are seen quite distinctly. In the further progress of the disease, rapid disorganization of the contents of the alveoli ensues. At the commencement of the disease the diffused syphilitic form is mostly of a lobular, peribronchial distribution. The lung, in this stage of the disease, which may be designated as a miliary syphiloma formation, is permeated by numerous very fine peribronchial nests or depôts of exudation.

According to Wagner, the microscopic examination shows the pulmonary tissue to be entirely airless, the alveolæ almost totally gone, and where any still remain they are only one fourth or one sixth as large as those that are seen in children who have already respired. The intra-alveolar tissue is greatly increased. This augmentation of the intra-alveolar tissue is due to the closely lying, medium-sized round free granules, about two hundredths of an inch in diameter; also some round, large-grained kernel-cells; in most places also a rich albumin and fat molecules, between which, in some places, simply atrophied or fatty degenerated granules and cells still remain; between the granules, cells, and molecules, a sparsely homogeneous, seldom distinctly fibrous ground substance is found, but nowhere is there any fibrous connective tissue to be seen. The mucous membrane of the bronchi is at the same time uniformly infiltrated; here and there some rough, thickened elevations are also to be seen, caused by an increased accumulation of thickened cells and granular infiltration.

The nodular infiltration which occasionally is found along with the diffused infiltration essentially displays the same structure as the latter, only the cells are found in greater abundance. Here, also, it is simply an exuberance of the interstitial tissue, only it is circumscribed in character.

These circumscribed, large nodes, the actual syphilomata of the lungs, are by far more characteristic than the diffused, and, while the latter are almost exclusively found in the new-born, the true syphilitic gummata are most frequently met with in the adult.

According to Fournier, the syphilitic gummata are rarely found singly; generally several of them are found at the same time, seldom, however, more than ten in a given case. Most frequently they are situated in the middle and lower lobes; occasionally they are also seen in the apices, in contradistinction from pulmonary tubercular deposits, which, as is well known, are met with in the apices mostly. They

vary in size, from that of a pea to that of an egg; generally they are roundish in shape, rarely ragged, grayish-red or yellowish-gray in color, homogeneous and slightly moist, distinctly circumscribed, but not encapsulated. According to Cornil, however, these nodules are sometimes surrounded by a glistening, fibrous zone. The pulmonary tissue, at the places occupied by the syphiloma, is entirely gone, and the parts between the nodes are often intensely infiltrated.

As already stated, the nodes, which at first are of a grayish-red or brownish-red color, and slightly moist, gradually become soft, the softening progressing from the center to the periphery, assuming more and more a yellowish color. At this time the gummatous nodes may partly or even entirely become absorbed, or be expelled through the bronchi, and in their places cavities of various sizes may remain, which gradually contracting, there then results a cicatricial puckering of the lung tissue, analogous to a condition found in tuberculosis.

In the diffused form of pulmonary syphilis, the differentiation from ordinary catarrhal inflammation of the lungs is as difficult to-day as it was twenty years ago, when Virchow stated that there was nothing characteristic between them. Still, the gummata of the lungs present characteristic signs sufficient to render them distinctive with some degree of certainty, especially where the other morbid lesions of syphilis are found; and these will scarcely ever be absent where the disease has made such inroads upon the pulmonary organs.

The gummata of the lungs are distinguished from tubercles of the lungs by their color and consistence, by frequently appearing on one side only, generally in the middle and lower lobes, seldom in the apices, by the fewness in number of the nodes, by their size, and finally, as Virchow has shown, in addition to the clinical history and concomitant morbid syphilitic lesions, by the presence of a connective-tissue-like matrix, constituting the pulmonary nodes.

Nevertheless, the difficulty of a positive diagnosis of pulmonary syphilis is increased by the fact that in many cases of syphilis, whether of the diffused or circumscribed form, phthisis pulmonum and tuberculosis very often become superadded in the course of syphilis—a fact that has been noticed by many writers on the subject.

Hence, only then will it be advisable to consider with certainty, even at the autopsy, any given case as being syphilitic disease of the lungs, where, in addition to the pulmonary lesions, other indisputable evidences of syphilis are found in the bones, liver, larynx, scars on the skin, etc.

As regards the etiology of the disease, it is now generally admitted that pulmonary syphilis is the result of an infection with syphilitic virus; but it is not always so easy to say in which stage of the syphilitic disease the lung has become involved.

In hereditary syphilis, the disease generally leads to an early death, most of the children dying, in fact, in a few days, or, at the most, weeks after birth; most, indeed, are born dead, and but few cases of congenital syphilis in which pulmonary syphilis developed itself and was recognized in early infancy are recorded in medical literature.

A very important point in the chronology of the dis-

ease is as regards the time of the appearance of the pulmonary lesion. In most of the cases found recorded in medical literature the disease in the lungs appeared between two and five years after the patient contracted the chancre; still, cases are also known where the disease of the lungs manifested itself as late as twenty years after. In the first case reported above, the pulmonary affection developed itself six, and in the second case some five years after the patient became infected with syphilis.

The symptoms of pulmonary syphilis, so far as the functional disturbances and the morbid alterations that can be demonstrated are concerned, vary, of course, according to the degree and duration of the disease, and also whether or not other organs are more or less involved in the disease.

The first symptoms of which the patients complain are usually a tickling sensation in the throat, slight cough, and a feeling of oppression in the chest. Afterward, cough, with or without expectoration, comes on. These symptoms gradually increase in severity. The difficulty in breathing increases, the cough becomes more severe, the expectoration, which hitherto has been very sparse and but slightly slimy, increases in quantity, becomes more purulent, now and then tinted with blood. As the disease progresses, severe hæmoptysis may also supervene, according to Leudet, and, in addition to the dyspnoea, intense spasmodic asthma may become superadded. Many of these symptoms, however—such as tickling and pain in the throat, dysphagia, hoarseness, etc.—are undoubtedly caused by the syphilitic ulcerations in the throat, which are almost always present in these cases.

These functional disturbances generally keep pretty even pace with the progress of the morbid lesions in the different organs.

The percussion of the lungs gives a dull, or even a perfectly flat sound, most frequently confined over the middle and lower lobes; less frequently does it extend to the apices. On auscultation, some undefined sounds and bronchial breathing are heard, generally accompanied by large and small bronchial *râles*; occasionally amphoric breathing and metallic tinkling are also heard, according to some writers; the vocal fremitus sometimes is quite feeble, and then again increased, according to the site of the indurated node.

This picture of pulmonary syphilis, in general, from the foregoing description of the symptoms and course, can not at first sight be distinguished from phthisis pulmonalis, as has been already observed; but, by a thorough examination and a careful history of the patient and of his condition, the true nature of the disease will soon be detected.

The course of pulmonary syphilis is generally slow and without any fever; still, it may be rapid in its course and attended by smart fever. Generally the system is not so much affected, nor so quickly undermined in syphilis of the lungs, as in phthisis. These are the great distinctive features in the course of the two affections, and serve to distinguish them from each other. Generally the disease remains confined to one lung, or to a portion of the lung, for a long time; later in the course of the disease, fever may supervene, and then the system becomes affected. Undoubtedly these are the cases where recoveries have taken

place, and cures are claimed to have been effected from phthisis by the administration of iodide of potassium.

The diagnosis of syphilis of the lungs rests mainly upon the following points: The functional disturbances and the demonstrable pathological alterations in the lungs, the course of the disease and the influence the treatment has upon it, the clinical history, and the coincidence of syphilis in other organs.

As has been already said, the functional disturbances are by no means characteristic enough to base upon them a positive diagnosis of specific disease of the lungs. All the symptoms described above are also met with in other pulmonary affections, especially phthisis.

Nevertheless, a thorough examination and observation of all symptoms furnish sufficient data for an accurate differentiation of syphilis from phthisis of the lungs. Hence, when a patient presents marked functional disturbances of the thoracic viscera, due to demonstrable pathological alterations in his respiratory organs, yet is not markedly emaciated, it will be well to bear in mind that syphilis may be at the bottom of the trouble, and he should be examined more closely than ever. If the patient is the progeny of healthy parents, was hitherto free from pectoral complaints, and now presents evidences of secondary, or, still better, of tertiary symptoms, the probability that he is suffering from syphilitic disease of the lungs is vastly increased. This probability attains to a certainty when the morbid alterations are unilateral, and chiefly in the middle and lower lobes, while the apices are free from disease.

Another point in the diagnosis of syphilis of the lung is this: That a phthisical patient may also become infected and syphilitic without his being for that reason affected with disease of the lungs of a specific nature; and, again, a pronounced syphilitic individual may acquire an ordinary phthisis which has nothing in common with pulmonary syphilis. The two morbid processes must be strictly differentiated from each other, however much they resemble each other, and however great an influence one disease may exercise in developing the other, for one disease always promotes the development and progress of the other.

It is an indisputable fact, as has been pointed out by Schnitzler, that persons who are prone to acquire catarrhal inflammation of the lungs will, under similar circumstances, more readily acquire syphilis of the lungs than others whose respiratory organs were sound previous to their becoming infected, and, conversely, syphilitic persons will frequently become consumptive who, without this cause (syphilitic infection), probably never would have become phthisical.

The same is true with the affections of the larynx. Those suffering from chronic catarrh of the larynx will, if they become infected, manifest the evidences of syphilitic disease of the larynx more frequently and more intensely than those who are free from laryngeal disease, very slight catarrhal erosions in the former quickly becoming transformed into specific ulcerations; conversely, it has been seen in cases of constitutional syphilis that phthisis of the larynx and of the lungs will be developed, though no other cause can be discovered than that of the specific disease.

The treatment of syphilis of the lungs can be disposed

of in two words—mercury and iodide of potassium—simply because these are the only two remedies in our pharmacopœia that exercise any influence over the disease under consideration. But we must bear in mind that the lungs, like other delicate and important organs—the brain, for instance—are liable to become irreparably damaged by delay. Hence, it will not do for the physician to try an expectant treatment, or direct the patient to migrate to a different clime. He should at once put the patient upon a full course of active treatment with mercury and iodide of potassium. Some physicians maintain that mercury should only be used in the secondary, and the iodide in the tertiary stage of syphilitic disease; but as it is not always possible to separate the different phases of the disease, and as it is by no means certain to which of the stages of syphilis the pulmonary complication belongs, it will be found necessary to administer both these remedies at the same time. I am certain that the efficacy of the iodide is increased by the addition of small doses of mercury, say one twentieth to one twelfth of a grain of the bichloride three times daily; of the iodide I give comparatively large doses—from half a drachm to one drachm three times daily. For the anæmia and the debility accompanying this condition, the various preparations of iron, especially the potassio-tartrate, and the best hygienic measures and food, will be necessary.

Book Notices.

A Treatise on Fractures. By LEWIS A. STIMSON, B. A., M. D., Professor of Surgical Pathology in the Medical Faculty of the University of the City of New York, etc. With three hundred and sixty illustrations on wood. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. xvi-33 to 598, inclusive.

An excellent book, as sensible as it is plain and unassuming. Without any attempt to give himself prominence by quoting a long list of his own cases, Dr. Stimson has written a thoroughly practical volume, which, while a valuable guide to the student, will constantly lead him to depend upon his own resources. The one effort of the author seems to be to convince his reader that in the treatment of fractures no amount of theoretical knowledge, and no elaborate surgical appliances, can excel the most ordinary mechanical agents directed by good common sense.

The opening chapters deal with the varieties of fractures, their ætiology, diagnosis, and the general methods of treatment. Chapter VI treats of the processes of repair, and is clear and practical, avoiding the histological details which are so puzzling to the beginner in treatises on surgical pathology. Under the head of treatment (Chapter VIII) considerable attention is devoted to the plaster-of-Paris dressing, of which the author approves, though he adds cautiously that "its limitations, as well as its merits, must be recognized." "I should hesitate," he says, "to apply it immediately after the accident, if the patient could not be frequently seen during the next forty-eight hours."

It will be noted with some surprise that in such a work as this so little attention is given to compound fractures. Whether or not the writer judges that no written descriptions can equal practical experience in the treatment of this important class of injuries, certain it is that only nine pages are devoted to the subject. The antiseptic method and that of "through-drainage" are briefly described, but for additional information the reader looks in vain in the subsequent chapters.

With Chapter XII begins the discussion of special fractures, those of the skull, the vertebrae, and the bones of the face being first considered. The chapters on fractures of the upper extremity will be read with interest and profit, though it is to be wished that the paragraphs on diagnosis and differential diagnosis were more complete. The discussion of Colles's fracture is quite exhaustive; in fact, it seems as if a disproportionate amount of space had been allowed to it.

Chapters XXV to XXVIII, inclusive, deal with fractures of the lower extremity; that on fractures of the femur is commendable as to its length and thoroughness. Scattered throughout the book are numerous valuable statistics, for which the author is largely indebted to Gurlt. Frequent reference is made to the work of American surgeons.

The volume is attractively set forth, with clear type, excellent illustrations, and both a table of contents and an index. We prophesy its future usefulness and popularity, since it avoids needless details, and is not overcrowded with descriptions of cumbersome and unpractical surgical apparatus. While the student may at times complain of too great conciseness, especially in the subject of diagnosis, he will, on the other hand, be spared elaborate dissertations on treatment, and will be taught to think out each case for himself as it occurs. The book is characterized by a total absence of anything like egotism. It expresses the results of combined experience, not the theories of an individual.

A Text-Book of Pathological Anatomy and Pathogenesis. By ERNEST ZIEGLER, Professor of Pathological Anatomy in the University of Tübingen. Translated and Edited for English Students by DONALD MACALISTER, M. A., M. B., M. R. O. P., Fellow and Medical Lecturer of St. John's College, Cambridge. Part I—General Pathological Anatomy. London: Macmillan & Co., 1883. Pp. xvi+360. [Price, \$3.50.]

This is an excellent translation of Professor Ziegler's manual, a work intended to be somewhat elementary, yet coming within the scope of a scientific treatise. Though adapted to the use of the beginner, the notes and references added by the author and the translator, and the interesting chapter on parasites, will render it of value to the more advanced student.

The general plan of the book (if there is one) is somewhat irregular. The initial section, on monstrosities, is unnecessarily extended, while the succeeding section, on the important subjects of hyperæmia and anæmia, hæmorrhage and embolism, is most incomplete. Under Sections III and IV, on disturbances in nutrition, are included all the forms of degeneration. The definitions are brief, but clear, and are fully illustrated by excellent woodcuts.

Under Section V, on inflammation, are included not only the different forms ordinarily mentioned in works on general pathological anatomy, but the growths which the author terms "the infective granulomata," such as tubercle, gumma, and lupus. The discussion of tubercle will be read with considerable interest, in view of the recent experiments of Koch, with whom Ziegler seems to be in full accord.

Section VI is devoted to tumors, and is the best in the book, in our opinion, as the author speaks more from his own experience. He takes occasion to differ from Cohnheim in regard to the pre-natal origin of morbid growths, and, as the result of his personal experiments and observations, rejects the possibility of secondary cancerous formations arising by a transformation of pre-existing tissues. His explanation of the etiology of tumors is rather obscure, as he speaks of the "intrinsic predisposition" of a tissue to a certain form of morbid growth. The closing section of the book is devoted to parasites, Chapter XXX, on

bacteria, being exhaustive. The reader will find a clear statement of all that is at present known with regard to these organisms, while the text is enriched with numerous references. Ziegler is an enthusiastic believer in the parasitic origin for many diseases. He even goes so far as to accord to each bacterium "special physiological properties," though he affirms that he does not believe that "the specific bacterium constitutes a distinct species in the biological sense." A carefully prepared index of authors and subjects concludes the book.

The work of the translator is above criticism. He has avoided idioms and long, awkward sentences, and has given us clear, readable English. The woodcuts are new and beautifully executed, and are evidently faithful copies of nature. It is refreshing to look at a drawing of a microscopic section and feel that it has not been constructed largely by the aid of the artist's imagination.

BOOKS AND PAMPHLETS RECEIVED.

A Year's Work in Ovariectomy. By William Goodell, M. D., Professor of Clinical Gynecology in the University of Pennsylvania. [Reprint from the "Medical News."]

The Dispensatory of the United States of America. By Dr. George B. Wood and Dr. Franklin Bache. Fifth edition, rearranged, thoroughly revised, and largely rewritten. With illustrations. By H. C. Wood, M. D., Member of the National Academy of Science, etc., Joseph Renington, Ph. G., Professor of Theory and Practice of Pharmacy in the Philadelphia College of Pharmacy, etc., and Samuel P. Sadtler, Ph. D., F. C. S., Professor of Chemistry in the Philadelphia College of Pharmacy, etc. Philadelphia: J. B. Lippincott & Co., 1883. Pp. viii+1,928. [Price, \$8.]

The Practitioner's Ready Reference-Book. A Handy Guide in Office and Bedside Practice. By Richard J. Dunglison, A. M., M. D., etc. Third edition, thoroughly revised and enlarged. Philadelphia: P. Blakiston, Son & Co., 1883. Pp. x+529. [Price, \$3.50.]

On the Relation of the Chest Movements to Prognosis in Lung Disease, and on the Application of Stethometry to Examinations for Life Assurance. By Arthur Ransome, M. D., M. A. (Cantab.), Physician to the Hospital for Consumption and Diseases of the Throat, Manchester, etc. With illustrations. London: Macmillan & Co., 1882. Pp. ix+100. [Price, \$2.50.]

A Treatise on Insanity in its Medical Relations. By William A. Hammond, M. D., Surgeon-General United States Army (Retired List), etc. New York: D. Appleton & Co., 1883. Pp. xiii+9 to 767, inclusive.

Materia Medica, for Physicians and Students. By John B. Biddle, M. D., late Professor of Materia Medica and General Therapeutics in the Jefferson Medical College, Philadelphia. Ninth edition, revised, rewritten, and enlarged, in accordance with the Sixth Revision of the U. S. Pharmacopœia, by Clement Biddle, M. D., U. S. N. With numerous illustrations. Philadelphia: P. Blakiston, Son & Co., 1883. Pp. xx+17 to 537, inclusive. [Price: cloth, \$4; sheep, \$4.75.]

Transactions of the New York Academy of Medicine. Second series, volume three. Printed for the Academy, 1883. [p. xl 205.]

Observations on Lithotomy, Lithotrity, and the Early Detection of Stone in the Bladder, with a Description of a New Method of Tapping the Bladder. By Reginald Harrison, F. R. C. S., Surgeon to the Liverpool Royal Infirmary, etc. London: J. & A. Churchill, 1883. Pp. 71.

The Symptoms and Diagnosis of Malaria in Children. By L. Emmett Holt, A. M., M. D., etc. New York: William Wood & Co., 1883. [Reprint from the "American Journal of Obstetrics."]

NEW YORK, SATURDAY, MAY 26, 1883.

THE ALLEGED OATH TAKEN BY FELLOWS OF THE
ACADEMY OF MEDICINE.

It has been represented to us that some of our readers have misinterpreted certain remarks made in the leading editorial article of our issue of the 12th instant. Those remarks were as follows: "As to the alleged oath, or something of the nature of an oath, we may say, in the first place, that nothing of the sort is to be found in the published requirements for fellowship, and that, being therefore not necessary to be signed, if it has any existence at all it has been interpolated surreptitiously, has been signed in ignorance if signed at all, and has not the slightest particle of validity."

Our informants have shown us that the following pledge is printed at the head of the list of signatures of the Fellows of the Academy: "The subscribers, being constituted Fellows of the Academy of Medicine, the constitution and by-laws of which are hereunto annexed, do hereby pledge their honor to conform themselves thereunto so long as they shall severally remain members thereof. In testimony whereof, they have hereunto annexed their respective signatures." Our informants very properly maintain that this pledge is "of the nature of an oath," that it has not been "interpolated surreptitiously," and that it has not been "signed in ignorance."

Now, we did not state that there was no pledge at all, for every corporate body pledges its members, either by implication or in an expressed formula, to abide by the rules of the organization. The gentlemen to whom we refer failed to understand our statement in the paragraph in question, simply because they omitted to connect it, as it ought to be connected, with a preceding passage in the same article, in which we said: "We have heard it gravely stated, for instance, not only that a Fellow of the Academy was bound to conform to its code of ethics so far as his individual acts were concerned, but that he was bound to uphold that code in every possible way—that, in fact, he was debarred from opposing the adoption or the maintenance of that code in other organizations, or even expressing an opinion unfavorable to it. It has been stated, too, that every Fellow signed his name, at the time of joining the Academy, to an engagement of the nature of an oath binding him to the course here defined."

We submit that the pledge that heads the list of signatures does not bind a Fellow of the Academy to "the course here defined." Therefore it does not fall within our statement. We said that, if there was any such pledge, it had been "interpolated surreptitiously," etc. It turns out, however, as we supposed, that no such pledge has ever existed. Consequently our statement was literally true.

THE TYRANNY OF DOGMATISM IN MEDICINE.

We have taken a great deal of satisfaction in the perusal of a collection of introductory addresses* by Professor Gairdner, of Glasgow, especially of that portion of one of the addresses in which "medical orthodoxy and heresy in the olden time" are considered. The addresses as a whole are replete with illustrations and reasoning of the most scholarly and creditable sort pertaining to the past and present status of the medical profession, and to the means by which medicine is likely to be most advanced; but the particular section to which we have referred has so direct a bearing upon the intolerance of dogmatism that no more wholesome reading, we are persuaded, could at the present time be offered to those who are inclined to play the part of the extremist in the contention now going on over medical ethics.

An exquisite specimen of the tyranny of dogmatism in the middle of the seventeenth century is given in the following passage quoted from Molière's "Le malade imaginaire," in which it is said of Thomas Diafoirus: "He is firm in disputing, strong as a Turk on his principles, never gives in an inch of his opinion, and pursues a verbal argument into the very uttermost recesses of logic. But, above everything, that which pleases me in him, and in which he follows my example, is that he attaches himself blindly to the opinions of our forefathers, and that he has never chosen either to comprehend or to listen to the reasons and the experiments of those pretended discoveries of our age touching the circulation of the blood, and other opinions of the same kidney."

The stubborn and protracted fight made by the regular faculty against the innovations of those who had the hardihood to investigate and talk about the medicinal properties of certain drugs that were held to be "quackish," simply because Galen and Hippocrates knew nothing of them, because they were vaunted by avowed charlatans, like Paracelsus, or because their vogue rested in some measure on the statements of the chemists, including such substances as antimony and opium—all this is recounted, and a startling picture is drawn of the rank spirit of the times that led men of essentially correct minds, such as Gui Patin, to bring every engine of repression to bear against those of their own number who displayed the slightest disposition to look into the merits of novel doctrines.

The warning we should take from this misguided and fanatical zeal of the past is not difficult to make out. It is, that we should free ourselves wholly from intolerance. We have already reached a state in which we can look calmly on doctrines that do not commend themselves to our understanding. We do not now persecute men on account of any sort of therapeutical belief, no matter how ridiculous it may seem to us. It would be better for us now if we had never done so, and it would be well for us if we could extend the same toleration into the do-

* "Medical Education, Character, and Conduct. Introductory Addresses," etc. By W. T. Gairdner, M. D., Professor of Medicine in the University of Glasgow, etc. Glasgow: James Maclehose & Sons, 1882. Pp. 80.

main of ethical opinions, and not jump hastily to the conclusion that whoever contends for what seems to us to be wrong is necessarily an enemy to the common good.

APOTHECARIES' MISTAKES IN DISPENSING MEDICINES.

In a paper recently read before the California Pharmaceutical Association, published in the May number of the "Pharmacist and Chemist," Mr. W. M. Searby discourses very temperately, and therefore all the more forcibly, upon some of the perils that beset even the most capable and painstaking apothecary in the daily pursuit of his calling, showing that circumstances may make it appear that he has committed a terrible blunder when in fact he has done nothing of the sort. Mr. Searby illustrates his remarks by the following incidents that have occurred in his own experience:

A young woman had a prescription prepared in my store. It contained muriate of ammonia, and some other not powerful remedies. When the bottle was empty, her physician ordered it to be refilled. Soon after taking the first dose out of the second bottle she commenced to vomit violently, and continued to do so for twelve hours or more. She said she had taken nothing but the medicine, so the doctor was summoned, and, from the symptoms, he suspected mineral poisoning. He came to me with the conviction on his mind that I had poisoned the girl, and at this time her life was in serious danger.

He brought with him a portion of the medicine, and a quantity of deep-green liquid, about the color of a strong solution of nitrate of copper, which she had ejected from the stomach. Fearing that I might possibly have blundered in some unknown and unaccountable manner, I tested the medicine, and found it free from poison. I asked the doctor to send the remainder of the medicine to an analytical chemist, which he did, and the result was my vindication. In the mean time, however, the girl stoutly maintained that she had been poisoned, and her employers were strongly inclined to believe her. During the investigation I was the victim of unwarranted suspicion, and, if the prescription had only called for one dose of medicine, it would have been impossible for me to clear myself, for as it afterward transpired that she had once before attempted suicide by arsenic (which was not known at the time of this event), and all the symptoms this time favored arsenical poison, I should probably to this day have been credited with dispensing arsenic in place of muriate of ammonia.

In the other case, a woman had a prescription for an ordinary tonic made up in my store. Soon after she had taken the first dose she manifested clear symptoms of poisoning by strychnia. The physician was quickly summoned, and, by the use of proper remedies, fatal results were averted, though her life was in the greatest danger. Of course, suspicion at once fell on the apothecary, but a closer examination of the phial showed a small crystal caught in between the neck of the bottle and the cork. This looked and tasted like strychnia. Surely, the doctor thought, no pharmacist would put strychnia into a bottle in that way. Diligent search was made, and an empty strychnia bottle found in the woman's pocket. This cleared up the mystery. When asked why she had put the poison into her medicine, she replied she wanted to get the doctor into trouble, because he had annoyed her, and she wanted to die in such a way that he would get blamed for killing her. But her criminal insanity came near being disastrous to me instead of the doctor. Had the tell-tale bottle not been found, an analysis of the medicine would have shown conclusively the presence of a large amount of strychnia, and how could the pharmacist prove that he had not put it there? He surely would have received credit with the public for having dispensed poison, and his business would undoubtedly have suffered greatly—perhaps irreparably.

There are few things that seem to give more solace to the ordinary human being in affliction than, to throw the blame of

his bereavement on some fellow-mortal; and the pretext for doing so is often of the flimsiest. The bare assertion of a chatterer of this sort has its damaging effect on the victim's peace of mind, even if it does not work injury to his business or to his social standing. No matter how baseless the charge, by frequent repetition it tells with the multitude, always ready to see any flaw that imagination or malice can conjure up. How much more must that man suffer who, as came near being the case in the instances here quoted, finds himself surrounded by a web of circumstantial evidence that he can not break? Surely none better than medical men can appreciate the distressing position of a pharmacist under injurious allegations that are supported by all the known facts in the case, however strong the accused may be in the consciousness of his own innocence; and, on that account, members of our profession ought not only to be the last to press the force of such circumstances, but, on the contrary, to urge the element of doubt in defense of the person so unfortunately situated.

AN OUTBREAK OF TRICHINIASIS IN SPAIN.

A RECENT number of the "Gazette hebdomadaire de médecine et de chirurgie" contains a portion of a letter addressed by Dr. A. L. Henriquez, of Malaga, to the editor of the "Gaceta Médica de Barcelona," recounting several cases of trichiniasis observed in Malaga last February. In one instance the patient was known to have eaten of American ham, and the ham was found to be trichinuous. In several other cases sausages were mentioned as the only article of food to which suspicion could attach. The sausages, however, do not seem to have been examined, nor are we told from what country they were obtained, although the American origin of the ham in question is set forth in italics.

If our European contemporaries would take a little pains to repress their seeming exultation when they find themselves able to trace an outbreak of this sort to American pork, they would strengthen the hands of those in this country who are endeavoring to impress upon the Government, and upon the gentlemen of the pork trade, that it is better to try to make the American hog what he ought to be than to follow the policy of denying that he is trichinuous. As it is now, the force of the observations they publish is decidedly weakened by the obvious animus that pervades the accounts.

THE NEW-CODE CAMPAIGN.
